THE

TELEGRAPHIC JOURNAL:

A

WEEKLY RECORD OF ELECTRICAL PROGRESS.

VOLUME I.

London:

TRUSCOTT, SON, & SIMMONS,

SUFFOLK LANE, CANNON STREET, E.C.

1864.

LONDON:

PRINTED BY TRUSCOTT, SON, & SIMMONS,
Suffolk Lane, City.

TO OUR READERS.

WE this day complete the first half-yearly volume of the *Telegraphic Journal*. In the outset we expressed our determination to fairly represent every interest in telegraphy:—the company, the electrician, the engineer, the superintendent, the clerk, and the messenger, each in turn has received consideration. Where abuses have been found to exist, we have exposed them fearlessly; where vested interests have been set up against the public good, we have administered rebuke; where temporising with valuable inventions has been found to impede the due development of science, it has been denounced; and where authority has been unduly exerted, to the manifest injury of the employés of our large companies, these columns have been open to the plaints of the sufferers; but whether we have fulfilled all our promises is a matter on which we in delicacy refrain from expressing an opinion.

Twenty-five years ago Messrs. Cooke & Wheatstone established the first line of telegraph on the Great Western Railway, and so rapid has been the extension of the system that we are now enabled to announce that the capital of every kingdom of importance is in direct communication. England is in a position to correspond with the Government of her Indian empire in the brief space of three days, which time will be considerably diminished on the completion of the overland section of the Persian Gulf telegraph; and we hope in the autumn of next year to be able to record the connection of Europe with America *viâ* the Atlantic and Russo American telegraph routes. Submarine telegraphy, by which these marvellous results have been achieved, is still in its infancy. On the questions of insulation and protection of subaqueous cables, doctors disagree, but day by day knowledge of the conditions under which submarine electrical communication can be attained increases, and we purpose to keep our readers *au courant* with the latest improvements and discoveries in oceanic telegraphy. Many erroneous views still obtain on the two last-mentioned branches of the art, and our observations and experiments to determine the cause of past failures have proved that mishaps result, not so much from faults in the electrical arrangements as from defects in the mechanical construction of cables, or from the violation of conditions which must ever be observed in paying them out from vessels into the sea.

It has been our privilege within the past six months to be consulted upon the feasibility of several new projects, to examine many new inventions calculated to improve and simplify the art of electro-telegraphy, and to report numerous discoveries in electrical science. In cases where we have recognised sterling merit we have never failed to give encouragement, and to report favourably; but several contrivances have been brought under our observation, distinguished by ingenuity and originality of design, which, on examination, proved to be totally inapplicable to practical purposes. We have, therefore, been not unfrequently compelled to pronounce opinions adverse to those entertained by inventors of their appliances. This course is the only one open to journalists devoted to science by an *amour propre;* and whenever our opinion is solicited we shall preserve the same even-handed justice in determining the merits or demerits of any design submitted to our consideration as we have maintained hitherto.

Our readers will be anxious to learn something of our present position and future prospects. It was hardly to be expected that success could be achieved until we had demonstrated our earnestness, and in part realised the promises held out in our first number. Time has shown that as the *Telegraphic Journal* becomes more generally known its circulation increases. It is in contemplation to publish from time to time chapters on Applied Chemistry, Metallurgy, Meteorology, and other of the contemporary sciences, and thus to make the *Telegraphic Journal* the *vade mecum* of the student, and a work of reference to the philosopher. During our brief career an interest has been awakened among the directors and shareholders in telegraph companies—a sphere remote from our anticipations of influence—and among telegraphists on the continent and in America, which has materially enhanced the value of our journal, and rendered it a most efficient advertising medium. In our labours to achieve the present favourable results we have been materially assisted by friends and contributors in all parts of the United Kingdom. The news which we have published from time to time has been procured for our columns by the disinterested intervention of gentlemen engaged in various pursuits, to whom we take this opportunity of tendering our hearty thanks. It only remains for us to add, that the interests we seek to represent promise to rival in magnitude the most colossal undertakings of modern times, and it will be our endeavour to faithfully chronicle telegraphic progress, to watch vigilantly the development of the art, to promote as far as practicable the well-being of all persons engaged in telegraphy—in short, to make the *Telegraphic Journal* a compendium of fact, a record of scientific research, and a valuable addition to the literature of the age.

SUFFOLK-LANE, CITY, E.C.,
25th June, 1864.

INDEX.

AERIAL insulation, experiments on, 135.
Amenities, 38.
American patent commissioner on the policy of patents, the, 272, 283, 305.
An exclusively telegraphic journal, reasons for, 1.
An institute for telegraphists, 109.
A plea for the clerk, 97.
Application of electricity to domestic purposes, on the, 181, 193, 205.
Appointments on the telegraph staff of India, the, 289.
Atlantic Telegraph Company, 140, 141, 165.
Atlantic telegraph, the, 61, 145, 201, 210.
Automatic telegraph of Mr. Thomas Allan, C.E., the, 135.
BONELLI'S Electric Telegraph Company, 157.
—— telegraph, 217.
—— typo-electric telegraph, 27.
British and Irish Magnetic Telegraph Company, Limited, report of the, 87, 102.
CABLES, submarine, 63.
Colonial telegraphy, 8, 43, 103, 250.
Conservation of force, the, 257.
Construction of telegraph lines, the, 43.
—— telegraphs, the, 241, 253.
Correspondence, 9, 22, 33, 44, 57, 69, 82, 93, 104, 118, 129, 142, 153, 166, 177, 190, 202, 227, 238, 250, 274, 285, 298, 306.
DABOLL'S fog signal, 210, 226.
Discharging or reversing apparatus for submarine cables, 7.
Distance signal for railways, M. Hipp's electric safety, 278.
Domestic telegraph, the, 218.
—— telegraphy, 241.
Dot and line alphabet, the, 174.
EARTH as a conductor, the, 160.
Electric and cosmical, 115.
—— and International Telegraph Company, 7, 68, 80.
—— barograph, Sissling's, 196.
—— communicator, Sax's, 110.
—— light and photography, the, 247.
—— telegraph in Europe and America, the, 290.
—— telegraph staff of India, Government appointments on the, 7.
Electrical discoveries, 137, 148.
Electricity, lighting gas by, 247.
Electro-deposition, new process of, 67.
Electro-magnetic induction machine, 285.
—— phonograph, the, 111.
Experiments on aerial insulation, 135.
FAULTS in insulation, 158.
Fire brigade telegraph, the, 37.
Firing gunpowder by electricity, 291.
Floating Telegraph Station and Light-ship Company, Limited, 254.
Fog signal, Daboll's, 210, 226.
GILMORE AND PREECE'S ship-steering telegraph, 136.
Gisborne's steering and engine signal apparatus, 6.
Government appointments on the electric telegraph staff of India, 7.
HALF-YEARLY reports of telegraph companies, the, 85, 133.
How to popularise telegraphy, 73.
IDENTITY of lightning and electricity, the, 243.
India telegraph department, 33.
Indian telegraph cable, the, 149.
—— telegraph, the, 159.
—— telegraphy, 97.
Indicating and dispersing fire-damp in mines, 134.
Induction, 266.
International Exhibition, 1862, the, 17, 26, 41, 52, 65, 76, 87, 100, 113, 125, 138, 152, 162, 171, 186, 197, 207, 222, 233, 244, 255, 268, 278, 292.
Iron wire, the manufacture of, 110.
John Watkins Brett, 6.
Joints in the insulated cores of submarine cables, 301.
Jones's portable galvanometer, 79.
LAND telegraph to Hong Kong and the Chinese ports, 257.
Law intelligence, 21, 44, 91, 202, 263, 274.
Lewis's permutating telegraph switch, 230.
Lighting gas by electricity, 247.
Lightning and electricity, the identity of, 243.
—— dischargers, 169.
Line of telegraph, to erect a, 17, 28, 52, 75.
London District Telegraph Company, Limited, 89.
MAGNETIC calms and earth currents, on, 161.
—— rheometer, the, 99.
—— storms and earth currents, on, 149.
Magneto-electricity, and its application to lighthouse purposes, on, 30.
Malta and Alexandria cable, the, 37, 61.
Manufacture of iron wire, the, 110.
Mauritius on the influence of heat and magnetism, 242.
Mediterranean Extension Telegraph Company, Limited, 55, 80.
Meteorologic telegraphy, 32.
Meteorological records, 270.
Method for ascertaining the velocity of projectiles, Mr. G. G. Newman's, 162.
Miscellanea, 11, 24, 35, 46, 59, 72, 95, 107, 132, 155, 168, 179, 191, 204, 216, 228, 240, 251, 263, 275, 287, 300, 307.
Miscellaneous experiments, 151.
Modern wonders in typo-telegraphy, 188.
Mr. C. F. Varley's translating apparatus, 14.
Mr. Cooke's pamphet or sketch of 1836, 189, 199, 211.
M. Hipp's electric safety distance signals for railways, 278.
Mr. R. S. Culley's new work, 3, 15, 39.
Mr. W. Ladd's new electro-motive engine, 153.
NEW process of electro-deposition, 67.
—— telegraph, the, 43.
—— Zealand exhibition, 1865, the, 111.
OCEAN telegraphs, 207.
Oceanic telegraphy, 39, 50.
On a magnetic experiment, 302.
On magneto-electricity, and its application to lighthouse purposes, 30.
On the application of electricity to domestic purposes, 181, 193, 205.
—— effects of external pressure on insulation, 122.
—— gas battery of Mr. Grove, and its theory, 79.
Opinions as to the practicability of deep sea telegraphs, 138.
Oran and Carthagena deep sea cable, the, 73.
—— submarine cable, the, 21.
Originator of submarine telegraphy, the, 258.
Our prospects, 134.
Our relations with America.—The Atlantic telegraph, 201.
PATENT laws, on the, 213, 224, 235, 248, 261, 270, 282, 295.
Patents, 252, 264, 276, 288, 300, 308.
—— recent, 12, 96.
Parliament and the telegraph interest, 2.
Parliamentary news, 131, 274, 285.
Permutating telegraph switch, Lewis's, 230.
Persian Gulf telegraph, the, 209, 258, 277.
—— expedition, the, 304.
Phonograph, the electro-magnetic, 111.
Porous cells, 123.
Portable galvanometer, Jones's, 79.
Practical development of the science of electricity, the, 164.
—— telegraphy, 13.
Pressure tanks for testing submarine cables, Reid's, 148.
Prices current of insulating materials, 12, 24, 36, 48, 60, 72, 84, 96, 108, 120, 132, 144, 156, 168, 180, 192, 204, 216, 228, 240, 252, 264, 276, 288, 300, 308.
Printing telegraphs, on, 184, 195.
Private telegraphs, 67.
—— telegraphy, 2.
Professor Morse and submarine telegraphy, 265.
Proposed competition between the Hughes and Bonelli instruments, the, 231.
Protection of ships' bottoms by electricity, the, 75.
RAILWAY and telegraph interests in Parliament, the, 121.
—— signalling apparatus, 153.
—— signals, 293.
—— train signalling, 99.
Reasons for an exclusively telegraphic journal, 1.
Recent discoveries in spectrum analysis, the metal indium and, 294.
—— patents, 12, 96.
Reid's pressure tanks for testing submarine cables, 148.
Remunerative speed on submarine cables, 157.
Report of the British and Irish Magnetic Telegraph Company, Limited, 87.
—— of the Telegraph Clerk's Provident Fund, 117.
Report of the directors of the Atlantic Telegraph Company, 140.
—— Electric and International Telegraph Company, 68.
—— Mediterranean Extension Telegraph Company, Limited, 55.
—— Submarine Telegraph Company, 118.
—— to the proprietors of the Telegraph to India Company, Limited, 56.
Reports of telegraph companies, the, 85, 133.
Reviews, 3, 8, 15, 39.
Richard Roberts' memorial, the, 297.
Royal Society, the, 142.
—— soiree, 237.
SAX'S electric communicator, 110.
Self-help, 62.
Ship-steering telegraph, Gilmore and Preece's, 136.
Simultaneous transmission of messages over a single wire in opposite directions, the, 232.
Sissling's electric barograph, 196.
South-Eastern Railway Company's telegraph, the, 123.
Special line for urgent messages, a, 254.
Steering and engine signal apparatus, Gisborne's, 6.
—— ships by telegraph, 127.
Stenography and telegraphy, 17.
Submarine cables, 63, 74, 98.
—— cables, discharging or reversing apparatus for, 7.
—— joints in the insulated cores of, 301.
—— Telegraph Company, Limited, 128.
—— Telegraph Company, report of the directors of the, 118.
—— telegraphy, 86.
—— telegraphy as an enterprise, 13, 25.
—— telegraphy, the originator of, 258.
TELEGRAPH Clerks' Provident Fund, the, 109, 117, 147.
—— companies, reports of the, 133.
—— in Spain, the, 221, 246, 280.

REASONS FOR AN EXCLUSIVELY TELEGRAPHIC JOURNAL.

THERE is scarcely a trade or profession but has its special organ of the press, and probably no department of Science, Art, and Manufacture which is not represented, and its interests forwarded by the same means. Where this is not the case the reasons are obvious. That such a provision is beneficial, however, is manifest from the facts of such journals having become an absolute necessity to that portion of the public whose cause and interest they advocate. On the other hand, where such special organs are wanting, it is notorious that certain bodies, trades, guilds, professions, sciences, or what not, have suffered not a little from an unnecessary seclusion and isolation.

The consequence of the discovery of a new science, or even the novel application of an old one, is not unfrequently the introduction of an enterprise, unique and unlooked for, affording scope for boundless ambition, and absorbing in its working out the labour, energy, and cares of thousands of hands, heads, and hearts, which assuredly, a few years back, never dreamed of being engaged in such an occupation.

Such now is Telegraphic Science, and the enterprise to which it has given birth. Although but a thing of yesterday it has absorbed a larger amount of capital in a shorter time than probably any other project set on foot, not excepting our great Railway undertakings. The individuals mixed up with its development, direct and indirect, may be counted by tens of thousands, many of them probably comparatively unacquainted with the mighty agent submitted, as we may say, to their manipulation; and yet this vast body remains virtually unrepresented by the press; nay, it has even lain under the imputation of failing to support a journal devoted to its interests. Assuredly there is something wrong here. A lack of patronage is not unfrequently the result of some deficiency in the persons seeking it. It is irrelevant to our present purpose, however, to inquire whether this has or has not been the case. We are satisfied that the many thousands engaged in telegraphic pursuits are prepared to support a journal conducted in an impartial spirit with talent and energy, and devoted exclusively to the interests of the large and influential class it seeks to represent.

Upon two accounts we base our claim to success, and we have no misgiving as to the result.

First, we design this to be a Telegraphic Journal *pure et simple*, to be kept intact from inroads of alien departments of electrical and other sciences, which can hardly be of interest to the bulk of those for whom we labour.

And, Secondly, we do not intend this to be so profound a scientific journal—stilted to such an unconscionable extent as to talk over the heads of the majority of our readers. Pure abstract science, and the theories which claim paternity thereto, can only be acceptable to, and find a response in the minds of a few of the large class whom it will be our privilege to address, hence while we shall be careful not to ignore the importance of these truly scientific lights of the world, and while we shall be most happy to make the Telegraphic Journal the medium of any new theory in electrical science and its adaptation to practical telegraphy, and while to this end we most cordially solicit the co-operation of these eminent gentlemen, we at the same time shall studiously avoid making these abstruse matters the predominant feature of the publication.

A small portion of our space will be devoted to the setting forth, in a popular and readable form, matters bearing on electrical and telegraphic science for the benefit of the student and the amateur; and, in order to adapt its pages to the capacities of ordinary minds, who, in all cases, form the majority of the reading public, we purpose making this journal the faithful record of all that transpires from week to week appertaining to the development of that science and enterprise whose organ it not unworthily seeks to be. By the capitalist therefore, who desires a good investment, while intent upon aiding the advance of that mighty agent—that distinctive characteristic of the latter decades of this nineteenth century which is to draw the ends of the earth together—our pages may be consulted with perfect confidence, since they will be the repertory of the all-important facts relative to the origin, progress, and standing of every company engaged in telegraphic pursuits, manufacturing and otherwise.

As a chronicle of passing events connected with this science—home, colonial, and foreign—it will be invaluable to the commercial man, no less than to the student of science, the electrician, and the engineer.

As a vehicle also for making known new inventions, improvements, and mechanical adaptations in telegraph cables, electrical instruments, &c., it will be peculiarly acceptable to the manufacturer and mechanician; while to the general public we hope to make it welcome by giving an epitome of valuable information on telegraph matters, written in such a way as cannot fail to be appreciated by those who wish to be posted up without much trouble to themselves.

We had proposed saying something specially on the advantages of a journal devoted exclusively to telegraphy and its attendant science, but we think what has already been written illustrates most forcibly that opinion. We have no wish to encroach upon the province of others. Surely there is a body sufficiently numerous engaged in the vocation we design to represent to support a journal of their own, and if so it is but reasonable they should wish such a periodical to be true to its character. We conceive that all that is required in the Telegraphic Journal is, that it should be the exponent of the science it represents, and an accurate reflex of current views, opinions, and transactions; and it could not properly be considered such if it should admit dissertations, arguments, and theories upon other sciences and subjects alien thereto. We shall better fulfil our duties in regard to telegraphy by devoting the whole of our energies and space to this subject alone in its elementary, theoretical, and what is no by means of the least importance, its commercial aspect.

The programme above indicated, if faithfully fulfilled, will leave but little space for making raids among other matters; nor are we desirous of thus presenting an incongruous medley to a class of readers, who, when they take up a telegraphic journal, expect to find its title borne out by the contents; and sure we are that the bulk of our readers are at one with us on this matter, and, indeed, it is mainly on this ground that we base our certainty of success; since a journal true to its character will recommend itself to those highly influential classes whose countenance and patronage will be the best proof of its merit, and thus render it a first-class medium for that description of support without which journalism could not exist.

PRIVATE TELEGRAPHY.

A retrospect of progress is at all times useful—a "taking stock" of our acquirements is sure to be of interest to some. There have been periods when progress has flagged, but this cannot be said of the times in which we live. Though oft repeated, not less true the phrase, "How would our fathers wonder at the sights which long familiarity has made with us quite common-place!"

The telegraph still ranks amongst the greatest wonders of the age. This is so universally allowed as not to need an argument for its enforcement; nor is it now our purpose to direct attention to the subject in its grand entirety; one single branch is all we claim regard to from our readers now—that branch is "Private Telegraphy."

A *Private Telegraph*. The union of these two expressions would have seemed absurd less than ten years ago, and why? The fact is, we have regarded telegraphs as public institutions *of necessity*. We thought it might be well enough for *companies* to have their lines, charging a certain sum for messages which they convey; we thought that even *Government* might have exclusive lines; but *private* individuals to have *their* private lines of telegraph was surely far beyond the bounds of reason. We remember when a single individual made every piece of telegraphic apparatus; others seemed to think a kind of mystery hung over them: an ignorance as great stops many individuals from having private lines.

The world of business owes a debt of gratitude to those who, throwing off the bonds of habit, felt that in possessing for their own exclusive use a line of telegraph, forming a link between their several establishments, bringing them virtually under one roof, almost under one eye, they would derive a benefit compared with which the cost would be as nothing.

Prejudice was once so strong against the use of even *public* telegraphs that we remember when a leading company employed an agent in the provinces to call attention to the value of the system, and show how useful it would be for general purposes. The public now no longer need an argument in favour of a *public* telegraph, but *private* telegraphy really needs an advocate. It ought need none, for whilst we readily accept our public lines as valuable helps to trade, as indispensable, in fact, as railroads, to private lines alone we look to meet a want which nothing else *can* meet. And yet, despite its manifest advantages, how little is the system taken up! Why are our larger towns alone to reap its benefits? Does not the country generally offer fields of promise? We feel assured that as the system spreads, so it will spread; we look upon it as a growing giant, and know that long before our children are our age its stalwart arms will circle every town, and not a house of consequence will be without a private telegraph.

We fear the public have imbibed a prejudice against our protége on grounds unfounded; the "clothes-lines" overhead are not attractive certainly, but they are not a necessary portion of a system, nor yet the "tripods" looming through the mist with hideous bend; the wires can be laid in pipes beneath the soil, under the kerb-stones possibly, and great advantage would arise from this arrangement.

Another objection to a private line—and this, we think, is based on firmer ground—is the uncertainty attendant on its action. We know a firm who, after adopting their own telegraph, at once dismissed five errand-boys, and when a breakdown happened to the line, their boys, accustomed to the work, were gone, and thus they felt a greater want than had they never trusted to their telegraph. Such causes of complaint will sometimes happen, we admit, for no machine is perfect; but much that is faulty may and will be remedied by better management; and healthy competition will go far to remedy the evils we allude to. But yet, with all the faults which now exist, the system must not, cannot die; the public will not long prefer to pay their sixpence, perhaps their shilling, for a telegram which may not ever reach its destination, or, if it does not come to grief in transit, may arrive too late for use, or possibly convey a meaning just the opposite of what was meant; they will not rather send a loitering errand-boy, or "cab it" in emergencies, and, perhaps, get "blocked" in going, when, by the possession of a private line, they have at their disposal—always at hand—upon their very desk—the means of holding conversation with their other house, and this with no more trouble than to ring a bell and call a clerk from an adjoining room. We feel assured that many firms pay yearly more for telegrams between their several establishments, with all the risk of *failure*, *error*, and *delay*, and lack the freedom, after all, of sending messages without regard to number, than it would cost them to possess a *better*, *quicker*, *private* line.

For hospitals, hotels, mines, factories, police and fire establishments, connecting stables with the house, or lodges with the servants'-hall, the nearest station with the country residence—these are a few amongst the many instances in which a private telegraph becomes invaluable.

We shall attack this subject at a future time; we leave it now, content with having drawn attention to its great importance. The public are the losers by its non-adoption, and our object is to some extent achieved if some who have hitherto held aloof should doff their prejudice, and fairly give a trial to the system.

PARLIAMENT AND THE TELEGRAPH INTEREST.

It has long been felt that the vast and increasing interest of Electro-Telegraphy is inadequately represented in the House of Commons, especially in its scientific and practical character and operations. The application of electricity to the purposes of telegraphy, although, comparatively, but of a recent date, has effected a mighty revolution in the means employed for the interchange of thought between individuals as well as nations, however distant apart, thereby rendering the Telegraph interest one of the most important in the country, not even second to the great Railway interest. We have had numerous discussions, occupying a considerable portion of the time of the House of Commons, during the last few sessions, on the various designs and contrivances suggested by scientific men, mechanicians and others for the best method of constructing iron-clad ships, heavy ordnance and small arms, and expensive and protracted experiments instituted to ascertain and determine their respective merits.

In the latter part of the year 1859 the Lords of the Committee of Privy Council for Trade caused to be appointed a committee, consisting of gentlemen well known for their scientific attainments and great practical knowledge, to enquire into "the best form for the composition and outer covering of Submarine Telegraph Cables." The committee was occupied for a considerable period in making numerous experiments, and in receiving the evidence of gentlemen conversant with the subject of telegraphy, and the report presented to Her Majesty's Government appears in the shape of a Blue Book, of some 500 folio pages.

It might have been expected that some notice of so important an enquiry would have been brought before the House of Commons, but such has not been the case. In all discussions and explanations relating to telegraphy, it has always been evident that the speakers were disinclined to express an opinion as to the merits of various forms of cables, of different sorts of insulating materials, or signal apparatus, although at the time some hundreds of thousands of pounds sterling of the public money were to be expended in the extension of telegraphic lines. The reason why so much silence prevails in the House upon so important a subject is difficult of conjecture, unless it be considered that it is so intensely scientific, and mysterious withal, as only to be approached by a few of our profoundest philosophers and mathematicians.

We sincerely trust that, at the next general election, the friends of telegraphic progress will exert themselves to return into Parliament a few energetic men, scientifically and practically acquainted with the requirements of the great and rapidly-increasing interest of Electro-Telegraphy.

MR. R. S. CULLEY'S NEW WORK.*

IT has always been a subject of regret amongst telegraph engineers and employés that we do not possess in the English language any standard work on the Electric Telegraph. Those who enter that profession have to master its details and learn its intricacies through that hard taskmaster—experience. Those who, fortunately for themselves, are proficients in foreign tongues have no difficulty in acquiring the knowledge they desire from continental sources. The literature of France and Germany teems with excellent treatises on telegraphic subjects, but England is, unfortunately, deficient in that respect. We are happy to say that the deficiency has been supplied. Mr. Culley has written a most excellent treatise. It is addressed to those who really required such a work, the practical men of telegraphy, and it possesses the additional value of being published under the sanction of the Chairman and Directors of the Electric and International Company.

The work is divided into ten parts, in which are explained, in a very plain and lucid manner, devoid of all technicalities and theoretical speculations, the laws which regulate the application of electricity to telegraphic purposes; the methods adopted to detect the presence and whereabouts of faults and defects; the practical management of apparatus, and the general construction of lines, We observe, with pleasure, that Mr. Culley has been assisted in his labours by Messrs. C. F. Varley and W. H. Preece, and, with such help, united to the author's own talent and long experience in the fields of telegraphic science, he cannot have failed to produce a work acceptable to the profession, and valuable to the general student.

He has exploded the long-received notion that the needle telegraph is the general instrument adopted in England. The Morse system is that which is now universally employed on all important lines. He says:—

> The commercial value of an instrument does not depend upon the use of the ordinary alphabets, but upon the amount of work it will turn out, and its accuracy and freedom from derangement. The Morse instrument is at present unsurpassed in these respects, and it has been found that its introduction upon a circuit previously worked by the needle system reduces error to a very considerable extent. This arises from its signals being *recorded;* they can be read calmly and without flurry, and should an error arise it can be traced to the person in fault, thus inducing a far greater sense of responsibility.

The first part is devoted to a description of the general sources of electricity, and from a perusal of this the student cannot fail to acquire a full elementary knowledge of the various means employed to generate that supple force, and the laws which regulate its action. We regret to observe that he makes use of the exploded term "intensity." All the actions of the current can be explained and its laws propounded, by the terms *electro-motive force, tension,* and *quantity.* We even object to *electro-motive force,* and are content with simply *tension* and *quantity.* In dealing with the laws of Ohm, the first term may be necessary, but in all the practical requirements of telegraphic science, tension and quantity are quite sufficient to describe all the various dynamic phases of the current. It is much to be regretted that electricians cannot arrive at some unanimous determination on this vexed point. An eminent electrician has recently made "confusion worse confounded" by introducing Green's quaint old term "*potential.*" We have, in studying different works, to find out the meaning of the terms, and particularly so when we read French and German productions. Electro-motive force, tension, potential, density, intensity, and quantity, are mixed up in indescribable confusion. Every man adopts his own reading, and considers every other man's reading wrong. It would be well if the British Association were to take this matter up with the zeal and spirit they have shown in endeavouring to arrive at some universal standard of resistance.

The descriptions of the various internal workings of the battery, and the directions as to their care and use, are invaluable and unique. The telegraph clerk and lineman would do well to study carefully this part of the work. Very little trouble is taken at present, by our great companies, to engraft their employés in the rudiments and philosophy of their occupation. They are expected to teach themselves, and no trouble is taken to select such persons for service as have shown a natural aptitude and desire to follow scientific pursuits. A telegraph clerk is left in charge of a station who has no more idea of the nature of a current than he has of the interior of the moon; and a lineman is left to the care and charge of his batteries, with a knowledge of their internal operations as profound as his notions of the metaphysical relations between man and the lower animals. The publication of Mr. Culley's work, and the dealing of the scientific portion of the subject in the style of this first part, will go a long way to remedy the evil.

Magnetism, and the connexion between magnetism and electricity, are dealt with in the second part, and simple instructions are given to perform an operation which a telegraph clerk is called upon to do more than any other, viz., that of magnetizing. Galvanometers of various kinds and shapes, electro-magnets and their doings, are detailed, and we only regret that Mr. Culley has not gone more fully into this branch of his subject. There is no doubt that those for whom this book is principally intended can acquire all the knowledge they require from elementary works, but it must be recollected that most of them have neither the opportunity nor the means to obtain such works, and a practical book ot this nature should, in reality, be a *vade mecum,* a manual in which they can obtain all the knowledge and information they desire. Its want of copiousness is the principal fault we have to find with the work, and if it reach a second edition we sincerely trust that its author will materially enlarge it.

Part III. on the resistance and the laws of the current, is, perhaps, the most valuable portion of the work to telegraphists, and it is one upon which Mr. Culley has evidently devoted much time. The way in which Ohm's laws are worked out and illustrated are particularly happy. The action of the earth, in telegraphic circuits and dynamic currents generally; its resistance, and the best form of earth-plates and contacts are examined. The part which the earth forms, whether it acts as a simple reservoir, or as an ordinary conductor, has ever been a bone of contention among electricians, and Mr. Culley, by adopting Gavarret's views, enrols himself with those who consider the earth as an ordinary conductor, and subject to all the laws of resistance and conduction.

With reference to earth-plates, he has the following valuable remarks:—

> A water or gas pipe is preferable to a plate, because of its larger surface. Care must be taken to connect to the main street gas pipe, as the joints indoors are frequently packed with white lead. It is best to use both water and gas pipes, so that, if one be under repair, the other shall complete the circuit; a well soldered connection could always be made.
>
> A narrow deep trench filled with coke, in which a copper plate, or what is better, a strip of lead, is buried, may sometimes be used, bearing in mind that the object is to expose as large a surface as possible.
>
> Plates must always be buried *flat,* and not coiled into a cylinder or spiral, and upright rather than horizontal.
>
> On connecting up a circuit of less than ten miles, it frequently happens that a permanent current appears on the instrument, arising from the earth-plates forming a battery. If an iron gas pipe be used for an earth at one end, and a lead water pipe or a buried plate of copper at the other, a current is always set up.
>
> It is necessary, then, to be careful that both earths be as nearly as possible alike, and to change one or both till the current ceases.

(*To be continued.*)

* A Handbook of Practical Telegraphy. By R. S. CULLEY, Telegraphic Engineer and Superintendent. London: Longman, Green, and Longman.

TELEGRAPHIC MEMORANDA.

THE following series of brief *Notices,* illustrative to some extent of the telegraphic operations of the past year, will, we trust, be acceptable to those of our readers who are interested in the progress and extension of land and submarine telegraphy. We shall endeavour to render the *Telegraphic Journal* a complete *record* of all such events and proceedings relating to Telegraphy. The meetings (as far as they relate to electrical science) of *scientific societies,* and those of Telegraph Companies, will be fully reported in our columns for the information of our scientific and commercial readers.

The Atlantic Telegraph Company announce that they had appointed a scientific committee, consisting of William Fairbarn, F.R.S., Joseph Whitworth, F.R.S., Professor Thomson, F.R.S., and Professor Wheatstone, F.R.S., in conjunction with their engineer and electrician, C. F. Varley, Esq., to advise on the most suitable form of cable for submersion in the great depths of the Atlantic.

A submarine cable successfully laid between Cagliari and Sicily.

In the first instance only a portion of the line was laid—from Cagliari to the Island of Maretimo—in consequence of the cable being too short for the whole distance, upon which the steamer "Hawthorn" was ordered to Malta to ship additional cable to complete the line, which was successfully accomplished.

The central station of the London and Westminster Bank connected with its branch establishments in Southwark and in St. James's, the work being executed by Messrs. Reid Brothers, and the instruments (Wheatstone's) supplied by the Universal Telegraph Company.

A large and extensive forest, composed almost entirely of the *ficus elastica* or caoutchouc tree, discovered in Madagascar by English explorers.

A large and influential meeting, held at the Public Sales Rooms in the Liverpool and London Chambers, for the purpose of hearing from the Right Hon. Stuart Wortley an explanation of the then existing position and favourable prospects of the undertaking for establishing an Atlantic Telegraph, Sir William Brown, Bart., presiding. The meeting was also addressed by several gentlemen of influence in the town, and a large amount of subscription promised towards carrying out the project, Mr. Rankin heading the list with a contribution of £500.

The French Government determine to institute a series of experiments with the typo-telegraph, invented by M. Bonelli, with a view of its adoption on some of their principal lines.

The Universal Private Telegraph Company issue a new prospectus, the board having been strengthened by some Manchester names. About 2,000 of the 7,600 shares of £25 each are offered to the public.

The French Emperor's speech, consisting of nearly 1,360 words, or 6,800 letters, transmitted from Paris to London in twenty minutes, four wires being employed.

Experiments made with Hughes's printing telegraph between London and Birmingham, when a large number of gentlemen interested in the science and practice of telegraphy attended by invitation at the central office of the United Kingdom Telegraph Company, Gresham-house, to witness the working of the instrument. The following noblemen and gentlemen attended:—The Right Hon. the Lord Mayor, M.P., Lord Ranelagh, Lord Alfred Churchill, M.P., James Wyld, M.P., Sir Frederick Smith, M.P., the Hon. A. S. Kinnaird, M.P., Joseph Somes, M.P., Sir Robert William Carden, Sir Daniel Cooper, Lieutenant-Colonel Patrick Stewart, Roger Cunliffe, Esq., Thomas Hankey, Esq., &c. The exhibition of the instrument pleased and surprised all present.

The Colonial Parliament of New South Wales authorise the construction of extensive lines during the year 1863.

The Telegraph to India Company (Limited), formed for "the special object of utilizing the cable laid down by the Red Sea Company from Suez by Aden to India," publish their report, in which it is stated that the station at Tubal was discontinued, and that a lease had been granted to Messrs. Glass, Elliott, & Co., of the Alexandria and Suez line, for four years, at a rental of £2,500 per annum, and that the Company had "applied for and obtained the sanction of his Highness the Viceroy of Egypt to construct a line to El Arish, with a view of completing the further communication to Beyrout, Iscanderoon, or Aleppo, and so connecting the company's line with Constantinople by one about to be constructed by the Ottoman Government from Diarbekir on the direct line from Constantinople to India, by which means a portion—and, in case of accident to the direct line, the whole—of the India and China messages would pass through the company's line."

The construction of a line of telegraph from Cape Town to Graham's Town agreed upon.

A severe gale, causing considerable damage to lines of various telegraph companies, especially in the north of England.

A telegraph line, constructed in the interior of the tube of the Pneumatic Despatch Company by Messrs. Reid Brothers, between the branch post-office in Seymour-street and the railway-station, Euston-square.

A very interesting historical and statistical paper, read before the Society of Arts by T. A. Masey, Esq., "On Submarine Telegraphs," which led to a protracted and important discussion, in which the following gentlemen took part:—Thomas Webster, Esq., F.R.S., Rear-Admiral Elliott, Dr. Wallich, Admiral Sir Edward Belcher, Colonel Shaffner, Captain Selwyn, R.N., John Macintosh, Esq., Cromwell F. Varley, Esq., &c.

The second ordinary meeting of the Telegraph to India Company held at the London Tavern.

A committee of naval officers appointed in Washington, United States, to inquire into the practicability of connecting all the naval and military stations between Fortress Monroe and New Orleans by submarine telegraph cables, and an application was made by Messrs. Glass, Elliott, & Co., to manufacture and submerge cables connecting all the points between Washington and New Orleans.

The Electric and International Telegraph Company issue their half-yearly report. The revenue of the half-year amounted to £117,074, which exceeded by £6,009 that of the corresponding period of 1861, and a dividend of £3 10s. per cent. declared for the half-year. The directors state that the cables and the general condition of the whole property was in every respect satisfactory. The engineer reports the mileage as follows:—

Miles of line	7,597
Miles of wire	35,066
Number of instruments	4,003

The first report of the Universal Private Telegraph Company published, showing the extent of the company's lines in various towns, and accompanied with a balance-sheet, showing a profit of £1,017 6s. 3d.

The London District Telegraph Company issue their half-yearly report, showing that the company continued steadily to progress:—

Year.	Net Receipts. £ s. d.	Number of Messages.	Stations open.
1860	1,609 19 1	73,480	52
1861	4,729 17 5	142,724	77
1862	7,955 7 10	251,548	84

A paper read before the Society of Arts by Thomas Webster, Esq., V.P., F.R.S., on Submarine Telegraphy, which gave rise to a considerable amount of discussion, in which the following gentlemen took part:—Fleeming Jenkin, Esq., C.E., Thomas Allan, Esq., Walter Hancock, Esq., Dr. Collyer, C. F. Varley, Esq., — Huxley, Esq., the Right Hon. J. Stuart Wortley, C. W. Siemens, Esq., F.R.S., T. A. Masey, Esq., Rear-Admiral Sir Edward Belcher, Owen Rowland, &c.

A meeting of merchants, manufacturers, and others interested in an Atlantic Telegraph, was held in the Council Hall, Sheffield, to hear an address from the Right Hon. James Stuart Wortley, chairman of the Atlantic Telegraph Company, when the position and the object of the company were fully explained.

A new Telegraph Bill brought before Parliament, its object being to make general regulations in respect to all telegraph companies existing and future, but not to affect existing companies in respect of a past exercise of power.

Several large meetings held in provincial towns by the friends and supporters of the United Kingdom Telegraph Company, which resulted in a considerable accession of capital.

A deputation from Bonelli's Telegraph Company, consisting of the chairman and several directors, waited upon the Right Hon. T. M. Gibson, M.P., at the office of the Board of Trade, on the subject of the new Telegraph Bill.

A paper read at the Inventors' Institute by Captain J. Selwyn, R.N., on the rise and progress of submarine telegraphy, and especially as regards the various inventions used for the submergence of deep sea cables. A discussion ensued, in which several gentlemen connected with telegraphy took part.

The half-yearly meeting of the Submarine Telegraph Company held, when it was stated that during the past year 172,831 messages had been transmitted against 137,714 for the previous six months, and showing an increase of 35,167 messages; and that the receipts were £23,427 5s. 6d. against £18,517 18s. 8d., or an increase of £4,909 9s. 9d.

A deputation connected with the Anglo-Australian and China Telegraph, in reference especially to the portion of the line between India and Australia *vià* Java, had an interview with the Chancellor of the Exchequer.

A deputation on behalf of the British Electric Telegraph Company had an interview with the Right Hon. T. Milner Gibson and the Right Hon. W. Hutt at the office of the Board of Trade.

The directors of the Atlantic Telegraph Company announce that more than two-thirds of the first issue of preferential shares had been subscribed for.

The failure of one of the most important links in the Channel Island Telegraph Company's lines announced.

A large meeting held in New York, at which Mr. Cyrus W. Field

spoke upon the subject of the Atlantic Telegraph Company. Several resolutions were passed declaring confidence in the success of the undertaking, and subscriptions to the amount of £38,000 reported.

The Magnetic Telegraph Company announce that, through the successful submersion of a telegraph cable in the West of Ireland, they had placed Greencastle in connection with the whole European telegraphic system. The result being that the Canadian steamers would for the future be signalled at once on their arrival, and two or three hours gained in the transmission of news and despatches to the metropolis and other commercial towns.

Some interesting discussion took place in the House of Commons on the electric light and lighthouses.

The council of the Society of Arts, in accordance with the suggestion of Sir E. Belcher, appoints a committee to inquire into the subject of submarine telegraphy. The committee to consist of the following gentlemen:—F. A. Abel, F.R.S., C. Brooke, F.R.S., Captain Donnelly, R.E., Captain Galton, F.R.S., W. R. Grove, F.R.S., E. Hamilton, Esq., Professor W. A. Miller, F.R.S., Sir Thomas Phillips, F.G.S., Major-General Sabine, F.R.S., Thomas Sapwith, F.R.S., W. Spottiswoode, F.R.S., Thomas Webster, F.R.S.

A Report published by the superintendent of South Australian telegraphs on the proposed Anglo-Australian and China telegraph scheme.

The Atlantic Telegraph Company applies to Her Majesty's Government for a grant of a sum of money in addition to that which had been subscribed by the public.

Several additional lines of telegraphs constructed for uniting the various stations of the London Fire Brigade establishments: the wires being erected by the London District Telegraph Company, and the instruments supplied by Messrs. Siemens, Halske, & Co., of Westminster.

(*To be continued.*)

TELEGRAPH PROPERTY.

AMONG the numerous startling discoveries that have marked the first half of the nineteenth century, there is not one more wonderful in itself, or more astonishing in its operations and results, than the Electric Telegraph. It may now be considered as one of the necessities of the period, and so far as we can at present anticipate, there is no saying to what extent it will be employed. In fact, Electricity itself, is still but in its infancy, and has hitherto been but little developed, except for the purposes of telegraphing.

More wonderful than steam and, although yet but partially understood, still under almost perfect control; infinitely superior to anything at present discovered for all purposes of communicating whether far or near. We doubt not but that Electricity will command an important position, whether considered scientifically or in a more practical and commercial point of view.

So far as the utility of the Electric Telegraph is concerned, we are bound to acknowledge that, up to the present time, it has been more generally developed in America than in this country. This, however, is attributable to various local circumstances. In that country the postal services are not to be compared with our own; their principal cities and places of business are far more distant from one another than in this country; the Americans are naturally great patrons of anything of go-a-head nature, and these various causes have led to a comparatively low tariff and present use of the telegraph. In that country the dividends of the various Telegraph Companies vary from 10 to 7 per cent., and the shares are consequently reported as a safe and profitable investment. The Continental Telegraphs, on the other hand, are almost entirely in the hands of the various Governments, and no opinions can therefore be offered as to their commercial value. There is, we are glad to see, an evident disposition to reduce the tariff as much as possible in several countries, which will no doubt lead to a satisfactory result, both to the foreign telegraphs and our own.

Our present purpose is, however, to submit to our readers the great progress that has been made by the principal Telegraph Companies—those in operation in this country—as shown by a Parliamentary Return of Miscellaneous Statistics recently issued:

ELECTRIC TELEGRAPHS.

Statistics of Electric Telegraphs for the Use of the Public, in the United Kingdom, in each of the Years 1859, 1860, and 1861.

TELEGRAPH COMPANIES.	Length in Miles of Telegraph Lines.			Length in Miles of Wires used.			Number of Stations open for the Public.			Number of Instruments.			Number of Public Messages.

Submarine. (Telegph. to Calais, 24 m.; to Boulogne, 25 m.; to Dieppe, 78 m.; to Jersey, 30 m.; to Ostend, 70 m.; to Hanover, 280 m.; and to Denmark, 380 m.	—	—	887	—	—	2,484 Submarine.	—	—	474 in United Kingdom, and about 3,000 in Foreign Countries.	—	—	54 exclusively for Continental Traffic.	—	—	About 230,000 to & from Foreign Countries

* On 31st December, 1861, this Company had 123 agreements with Railway Companies and with Public Offices for the transmission of their Business Messages. The number of such Messages is not precisely recorded, but is estimated as amounting to three times the number of Messages sent by the general public. This Company had, on the same date, contracts for supplying intelligence to 175 Journals, and to 99 Institutions, but no record is kept of the exact extent of the matter transmitted. It is, however, estimated that this intelligence, in addition to the continental work passing over the Company's Submarine Cables, amounted, at the date referred to, to a total of 756,485 Messages.

† The number of Messages to and from the Continent transmitted jointly by this Company and the Submarine Telegraph Company, and the number of Messages for Railway Companies, Newspapers, and News Rooms, are not included with the messages for the public, but are estimated at about 250,000 Messages per annum.

‡ The South-Eastern Railway Company has no working arrangements with either of the Electric Telegraph Companies.

§ Exclusive of private telegraphs provided by this Company for firms and persons having two places of business.

The foregoing must be considered very satisfactory, more particularly, when it is considered that the large increase in the number of messages transmitted by the various Companies, has not led to a corresponding increase in their working expenses.

(*To be continued.*)

JOHN WATKINS BRETT.

In every age and in the progress of every science there are men who for ever stand out as landmarks in the history of the wonderful inventions which now constitute a large portion of the working material of our every day life. Such was Watt with the Steam Engine, Wedgewood with Pottery, and such was John Watkins Brett with the Submarine Telegraph.

Although several may claim the honour of the invention, yet none, I believe, will ever dispute the title of "Founder" of the Submarine Telegraph to John Watkins Brett.

How Mr. Brett first became associated with the science is best told in his own words. In his work on the *Origin and Progress of the Oceanic Electric Telegraph*, he says:—"My first idea of Submarine Telegraphs arose out of a conversation with my brother Jacob, early in 1845, when discussing the system of Electric Telegraphs as then recently established between London and Slough; and in considering the practicability of an entire underground communication, the question arose between us, 'If possible under ground, why not under water? and if under water, why not along the bed of the ocean?' The possibility of a Submarine Telegraph line then seized upon my mind, with a positive conviction, which led to the consideration of a plan for an entire new principle of Subterranean and Oceanic Electric Telegraphs.

"My brother being possessed of great natural mechanical talents, also at once occupied himself with the embryo model for a printing telegraph, to work by a single wire. Having completed our plans, my brother and I registered a company (June, 1845), for uniting America with Europe, by the very route since carried out, but at that time failed to obtain the attention of the public, it being considered too hazardous for their support. Having failed in July, 1845, in our offers to the English Government to unite Dublin Castle with Downing-street, I applied in 1846 to the French Government for a privilege to lay a Submarine Cable between Dover and Calais, which was accorded by Louis Philippe, and subsequently renewed by the Emperor of the French, and the present cable between Dover and Calais was laid on the 25th September, 1851, but an experimental line had been submerged the previous year, by which I passed the first electric message ever sent from one continent to another, which was printed by the instrument in Roman type. In 1847 I applied for a concession to the King of the Belgians, and, finally, in 1852, obtained this privilege, under which the second cable to the Continent was successfully laid on the 6th May, 1853, from Dover to Ostend.

"On the 19th July, 1852, the Act for the European and American Telegraph Company was obtained at my cost, and I laid down, by virtue of this Act, the underground lines from Dover to London, Birmingham, Manchester, and Liverpool.

"The great objects I continually had in view were the submarine lines eastward to India and westward to America.

"In June, 1853, I obtained the concessions from the French and Sardinian Governments for the Mediterranean, as part of the Indian line. In January, 1855, I entered into an agreement with the New York, Newfoundland, and London Telegraph to establish the Atlantic Line, and Mr. Cyrus W. Field having united with me to carry out this enterprise, the present Atlantic Company was formed in 1856 for that purpose."

It is unnecessary further to recapitulate in detail, as the circumstances are so well known, the part which Mr. Brett took in establishing the present system of telegraphic intercourse across the channel between England, the Continent, the Mediterranean and the Atlantic.

Much has been unjustly said against the exclusive privileges granted by different foreign governments to Mr. Brett, in ignorance of the great benefits which these same privileges have conferred upon the public. For instance, when the through communication was first opened between London and Paris, the charge for a single message was 17s. 6d., and Mr. Brett incessantly laboured until the price was reduced to the present charge of 5s., and he was one of the first to advocate the universal 1s. rate.

The science of Telegraphy has lost—if I may be permitted to use the expression—the father whose fostering care controlled and developed nature's mysterious and intangible agent, and taught the infant Submarine Telegraph first to lisp a few words across the channel in 1850, and lastly to speak across the Atlantic, and whose electric voice is now heard issuing from the depths of the ocean to the furthermost parts of the world, uniting shore to shore, annihilating time and space, and cementing amity and peace between the different nations of the earth. Surely this was a great and noble work.

With a mind so essentially practical, it is rare to find associated the finer qualities of a refined taste for art; yet in the instance of Mr. Brett, the intuitive gift of a painter early developed itself, and was matured by study; although his works as an artist are little known beyond his family, who possess many proofs of his talent as a painter, in the sketches made in a tour through America, and the highly finished drawings in their possession. His gallery of the works of the Old Masters, has been a source of admiration to all who have had the pleasure of viewing it. Nor was his taste only confined to pictures, as his collection of antiquities, bronzes, coins, objects of vertu and books attests. The death of this talented man has left a great blank in the circle in which he moved, for he was essentially one of nature's own gifted gentlemen. Gentle and kind in disposition, resolute in purpose, and endowed with great natural talent and vigour of mind.

By his first grand success in Submarine Telegraphy, Mr. Brett had linked together the Old World. It remained to achieve the triumph of connecting that Old World with the New, but he has not survived to witness the ultimate success of those efforts in which he took so large a share.

Like many other inventors, he had the mortification of experiencing some failures, but his conviction of the final success of the Atlantic Telegraph remained firm to the last; and although as a mere mercantile speculation, it has proved comparatively a failure, yet within a few weeks of his last illness, he was working hard to resuscitate the Company, and had the gratification of seeing the labours of himself and others crowned with success so far as a a sufficient subscription for a new cable.

Familiarity with the wonderful in the present age, renders us too careless in observing and appreciating the marvellous characteristics of scientific achievement, and too often, there is scarcely time for pause to give the laurels to the deserving individual, before another claims the wreath for yet greater intellectual and scientific triumphs. But in the world's race after distinction and honours, few men, heedless of fame, although inwardly conscious of greatness, have the nobleness to refuse a King's favour, because offered to them on a Sunday; or resign an Emperor's decoration in favour of a younger brother, lest he feel disappointed at not receiving an equal reward for labour that was shared.

The writer of this brief memoir, had the privilege of an intimate acquaintance with Mr. Brett for upwards of twelve years, and therefore had an opportunity of witnessing, and becoming acquainted with his many noble and estimable qualities; amongst them were conspicuous, piety and charity; of the first, it is hoped he has received the reward; of the second, he has left testimony in giving by his will, tithes of all he possessed.

Mr. Brett was never married, and died on the 3rd December, 1863, at the age of 58, and is interred in the family vault, in the churchyard of Westbury-upon-Trym, near Bristol, his birth-place.

T. A. M.

GISBORNE'S STEERING AND ENGINE SIGNAL APPARATUS.

Of all the numerous and important purposes to which electricity has been applied, there are but few which possess a higher claim to our favourable notice for its utility and the advantages it confers than the above simple, ingenious, and highly efficient apparatus. Its practical value is attested by its employment on board several of Her Majesty's ships, such as the steamship "Radamanthus," the iron-clad steamship, the "Royal Oak," etc., and also on board the Imperial Russian iron-clad steam-battery, the "Pervenetz," and in each the arrangement has given perfect satisfaction. By the means of the instrument the officer in charge of a vessel may, from any desirable position upon her deck, transmit his orders to the helmsman or engineer; and every such order will instantly appear in *printed letters* before the last-named officials, and remain in sight as long as may be required. Whatever may be the condition of the elements, the order is transmitted with absolute certainty, without possibility of mistake, and is accompanied by the ringing of a bell to command prompt attention. By a single motion of the engineer, or of the helmsman, the officer of the deck instantly receives the reply to his order, and at the same moment the *movement of the helm* is made known, with perfect accuracy, to that officer (inde-

pendently of the helmsman), before it is possible for the vessel to answer to it. This result is made certain, even though the weather should be so thick that the officer could not see an object only six feet from him. The patentee invites those interested in the application of electricity to so useful a purpose, to call and examine the apparatus, which is to be found at the establishment of Messrs. S. W. Silver & Co., Bishopsgate-street Within, and where its construction and its mode of action are fully explained.

GOVERNMENT APPOINTMENTS ON THE ELECTRIC TELEGRAPH STAFF OF INDIA.

In May next, twenty-five appointments will be made in the Telegraph department of the India Office, and as these will be given to candidates who pass most successfully a competitive examination to be held in May, it is necessary that all those who intend to compete, should at once take steps to qualify themselves. We are given to understand, that the candidates must be native British subjects, not less than eighteen, nor more than twenty-four years of age, and must either have passed two years in the service of a Telegraph Company, or as an articled pupil of a Telegraph Engineer, or must have given special attention to Chemistry and Physics at some School or College, recognized by the Secretary of State. These seem but easy terms upon which to enter for these valuable appointments, which range from £15 to £30 per month; but it is also compulsory that the successful candidate obtain in his examination at least 2,000 marks out of 5,000, in the various subjects to be selected by the Examiners. This will doubtless ensure a careful selection of competent young men to fill vacancies in a department that is viewed in the most important light by the Indian Board, and we shall look forward with much interest to the result of the examinations, so as to find if the subject of Electricity and Telegraphy is made part of a scholastic education. It has not hitherto been the custom of our chief Telegraphic Engineers to take articled pupils. The profession has been regarded hitherto as a branch of engineering scarcely so distinct as it should be, for it is one that to succeed, must not be mixed up with other branches. It requires an amount of care and study sufficient to occupy the sole attention of those who follow it; and the decision of the India Board will perhaps influence parents and guardians to adopt timely measures, so that in addition to the ordinary Mathematical Education so desirable for the proper appreciation of electro-statics, or electro dynamics, they may afford young men the opportunity of acquiring a practical knowledge of Electro-Telegraphy, by placing them "for two years in the service of one of the English Telegraph Companies, or as articled pupils of a Telegraphic Engineer."

We strongly recommend, that in public schools, the prizes should be varied by presenting to pupils some piece of philosophical apparatus, such as the Microscope, Electrical Cylinder Machine, Induction Coil, or Galvanic Battery. They can be obtained readily in such a form, as would prove not only interesting, but highly instructive to the student, who would then begin to form his mind upon the particular profession he would afterwards select. Should the Electric Telegraph prove a source of attraction to him, there would be no difficulty in finding one of the many Telegraphic Engineers who would accept him as a pupil, and with whom he would have ample opportunity of obtaining that practical information, without which, the aspirants to future appointments such as those to be awarded in May next, will seek in vain.

DISCHARGING OR REVERSING APPARATUS FOR SUBMARINE CABLES.

The Government telegraph to India have had made, by Messrs. Silver & Co., some of Mr. Andrews' (Secretary and Manager of the United Kingdom Telegraph Company,) pneumatic arrangements for line reversal currents, in line discharges of submarine circuits. The apparatus have been for some years exclusively employed, with the most satisfactory results, by the Submarine Telegraph Company, for working their long cables. According to the system employed by Siemens, the apparatus used for throwing in reverse currents, for relay stations, is fixed to the Morse train, and does not, therefore, admit of adjustments so as to throw in currents of greater or lesser duration; and an accident to the train stops the communication. Working from the key, direct from one station to another station, the key is held constantly on one side, so as continuously to send the reverse current. The same result is obtained in Bailey's system, and the practical consequence is, that the distant station must wait for the completion of the message before it can speak with the sending station, although the matter received may all be incorrect. In Mr. Andrews' arrangement those difficulties are obviated, and this advantage is very great, especially on rapid working ærial lines, where, to facilitate the regulation, the reverse current system is employed. Its importance, on submarine circuits, is also considerable.

The arrangement is as follows:—An ordinary pair of electro-magnets, vertically placed, and a horizontal bar, are provided; the bar is rather longer than those ordinarily used; the one end of this bar works between two insulated contact points, the upper one connected to the relay, the lower to the reversal battery, or the earth, according to the system employed, whether reversal or discharging. A spring on the under side of the bar is used, to lengthen the contact with the lower contact point. Attached to the under side of the bar, near the contact point, is a piston of German silver, with a valve formed by a round ball of alluminium, working in a socket open at the bottom; this piston and valve work up and down in a cylinder of ebonite, or other material, partly filled with chronometer oil. When the relay is attached, it sends the current from the local battery through the Morse writer, and the electro-magnet is the pneumatic arrangement. The armature of the latter brings down the bar and piston; the valve opens, and the oil passes through. On the current arising, the spiral spring draws up the bar, but as the oil can only pass slowly down again, between the sides of the valve and the cylinder, to fill up the vacuum created, the bar rises slowly, according to the strength of the spring and the stroke of the piston. The apparatus admits of such accurate adjustment, that the distant end, if desirous to speak, may do so at the end of each word, or between letters or sentences. For direct working, two small springs, horizontally arranged, and overlapping, but not touching one another, are placed under the ordinary Morse handle, and when the latter is depressed the two springs are brought into contact, and the local battery sends a current through the coil of the pneumatic apparatus as before mentioned; no resistance, therefore, is thrown into the line. The friction is almost nil, and a single cell will work the apparatus; the stroke required is also extremely short. The working does not vary, and the apparatus works with remarkable precision and certainty.

ELECTRIC AND INTERNATIONAL TELEGRAPH COMPANY.

Mr. J. S. Fourdrinier has retired from the appointment of Secretary to the above Company, after fifteen years of arduous service, during which time he has raised that Company's system from one comparatively small and insignificant to a most exalted position, both in a financial and business-like point of view. No one who knows what is involved in the organisation of a large telegraph system will deny that the labour is incessant, and compels the *Chef du Cabinet* to watch closely all the details of the concern. It is in our power to claim for Mr. Fourdrinier the utmost credit for his conduct in this respect. A more unwearying, conciliating, or faithful officer is not to be found in the ranks of the eminent men composing the staff of the Electric Company, and if the award of labour is success, then we shall surely not be denied, if we claim for the gentleman, whose services the Company now loses, the highest award, inasmuch as the status of the Company will bear comparison with any mercantile undertaking of the day.

In all its details—in every department—the duties of each and every one are carefully defined. An error in a message, delay to an express, interruption on the line, or derangement of the apparatus—no matter what the fault—there is no difficulty in deciding upon the party to blame, and thus while each knows his responsibility, he is careful not to be found wanting in his duty. Of this highly systematic state of things the late Secretary was almost, if not entirely, the founder, and we can readily speak of it as a personal point that he had a rule for everything It, in fact, was proverbial that he had so framed the rules and regulations of the Company's service that it was impossible to go out of the strict course of business without breaking them.

It is certain that few men could have grappled with a new "idea"—a system, which, as the late Mr. Ricardo once said, "had required even a new language," and have brought it so systema-

tically into a daily routine as to convey with such remarkable precision and regularity the interminable amount of business that now passes over the Company's system from the northern extremity of Great Britain to the Land's End. To any stranger, the wires of the Electric Telegraph Company, if drawn upon a map without showing their connections, would be an inextricable web. To arrange the working of such a system would be a Herculean task. The question of staff would lead one to think of the formation of a battalion. And this was, in fact, the chief secret of Mr. Fourdrinier's success. He recognised the duty of each officer in his grade; his was the responsibility. One hand guided the good ship, and he steered it well, and we are glad to know that he leaves the vessel in a sound condition, and with such a mark of approval from the directors as does credit alike to Mr. Fourdrinier and to the Electric Telegraph Company.

Mr. Fourdrinier is succeeded by Mr. H. Weaver, one of the oldest officers in the service, he having joined the Company in May, 1846, previous to its incorporation.

Mr. Weaver was resident on the Continent for several years as manager of the International Telegraph Company, and returned to England in 1859, replacing Mr. D. P. Gamble as Metropolitan Superintendent, in addition to the management of the Company's Continental business.

REVIEWS.

MAP OF EUROPE. Compiled from the most recent surveys, published for the Electric and International Telegraph Company, showing the system of Telegraphs with which they are connected. By H. WEAVER, Esq., Met. Supt. of the Electric and International Telegraph Company. London, 1863.

This is a valuable contribution, not only to the telegraph service, but as affording to the public at large a ready and intelligible means of ascertaining at a glance the vast and wonderful ramifications of the system of European telegraphy. The extensive employment of telegraphy for political, commercial, and private purposes has long rendered such a map highly necessary, and we hail with satisfaction its appearance, especially as it has been designed and constructed by a gentleman whose extensive information and experience in telegraphic matters are a guarantee as to its correctness and fidelity. The lines and stations are clearly and distinctly marked, and the various countries traversed are designed by a judicious system of colouring. Less than twenty-one years ago, in a language almost bordering on despair, the faithful and persevering inventors, Messrs. Cooke and Wheatstone, state, —"At the beginning of the year 1843 we were at our lowest point of depression. The patents remained almost unproductive, and we had incurred in various ways a considerable outlay." Let us trace on the map the short line at the time constructed between Paddington and Slough: to the west it has reached the western coast of Ireland, and terminates at Castlebar; to the east, leaving London, it passes through numerous counties and towns to the shores of the German Ocean, and continues its course beneath its waves to Heligoland, where, after another short submergence, a branch line extends to Copenhagen, Stockholm, and Christiana, the capital cities of Denmark, and Norway respectively. The main line proceeds, accommodating on its way the cities of Hamburg, Berlin, and Warsaw, &c., to St. Petersburg, on the banks of the Neva; thence to Moscow, and terminates at the city of Omsk in Siberia, on the frontiers of China!—a distance of some four thousand miles. A line extends from Moscow to Odessa, and from hence to Tscherkash on the banks of the Don. Another line, starting from Valencia, the proposed station of the intended Atlantic Telegraph Company, on the western coast of Ireland, after passing through Cork and several other towns, crosses the St. George's Channel, and runs along the western counties of England to the metropolis, from whence it proceeds south across the English Channel to Paris, Munich, Vienna, Pesth, Schumla, &c., to Constantinople, where it is ultimately to meet the great Indian line now in course of construction, when direct communication may be effected between the Irish shores of the Atlantic and Calcutta, in the remotest part of British India.

SILVER'S GUIDE TO AUSTRALASIA, and Itinerary to and in the Colonies of Victoria, New South Wales, Queensland, South Australia, Western Australia, Tasmania, and New Zealand. S. W. SILVER & Co., Bishopsgate-street, E.C.

A very useful compilation of some 150 pages. It contains a large amount of information upon all matters relating to the colonies, and several exceedingly well-constructed and coloured maps. We quote the following items on the subject of colonial telegraphy. Victoria has now "a network of telegraphs, extending over 1,500 miles, communicating with sixty stations; it spreads over the colony, and corresponds with the telegraphic system of South Australia, New South Wales, and Queensland." Of New South Wales it is stated almost all the chief towns are connected with Sydney by electric telegraph; and the New South Wales system is in communication with the Victoria, South Australia, and Queensland lines. The chief lines are:—1. The line from Maitland to Singleton, Murrundi, Tamworth, Armidale, and the southern frontier of Queensland, 400 miles. 2. From Bathurst to Sofala, Tambaroora, Louisa Creek, and Mudgee, 97 miles. 3. From Gundagai to Tarontta, Wagga Wagga, and Deniliquin, 700 miles. This line corresponds with the line from Deniliquin to Echuca, Castlemaine, Ballaarat, and other places in Victoria. 4. From Gundagai to Kiandra, Snowy River Diggings, 87 miles." In South Australia, "Three telegraph lines are open; the first two follow the lines of railway, and the third from Adelaide to Kooringa and Kapunda, and further on to the frontier corresponds with the Intercolonial Junction line which connects South Australia, New South Wales, and Victoria." In Tasmania "a line of electric telegraphs, 124 miles long, connect Hobart Town and Launceston."

The Directors of the London District Telegraph Company (Limited) have published a very useful little Almanack for the year 1864. It contains a list of all the Company's stations in London and the suburbs, with the scale of charges for the transmission of messages. The Almanack is published in such a form that it can be kept in the folds of an ordinary pocket book.

COLONIAL TELEGRAPHY.

UNDER the above heading it will be our effort to place on record the progress made in telegraphy in all our colonial possessions. The subject of Colonial Telegraphy is one of considerable importance, especially as its development must lead to the extension of our submarine system. We shall always be thankful to any of our subscribers who will kindly favour us with information upon the above important subject.

CAPE OF GOOD HOPE.—At least six months within the Government contract time we shall have the telegraph from Cape Town to Graham's Town completed. In selecting Messrs. Siemens & Halske for the execution of the work, the Cape of Good Hope Telegraph Company—most efficiently represented here by Mr. Wollaston—appear to have acted wisely, for, from all we understand, the work is done most substantially, and will, when finished, probably be one of the best-constructed lines of telegraph which has yet been erected, The Company has before it every chance of success. The meeting of Parliament next year in Graham's Town will put the practical working of the line to a test, and give proof of the incalculable benefit of a telegraph line running upwards of six hundred miles from one extremity of the colony to the other. By the time our friends in England have the opportunity of replying to letters leaving by the mail to-morrow, they may save some days in communicating with Port Elizabeth and Graham's Town by making use of the telegraph. We are informed that arrangements are in progress under which persons in England will be enabled to communicate with their correspondents at either of those towns, by sending their messages to the offices of the Company in London, paying one shilling extra for the postage to the Cape; the messages so sent being forwarded from Cape Town by telegraph, immediately upon the arrival of the steamer in Table Bay. This will be an immense advantage to the merchants of Port Elizabeth and Graham's Town. The line is already finished from Port Elizabeth to eight miles this side of Swellendam; and a working party is about to commence operations at Cape Town with a view of accelerating the completion of the remaining portion of the line. The Telegraph Company are going to construct a line of telegraph along the Wynberg Railway, and will place the Simon's Town wire on the poles, removing the Simon's Bay telegraph line from the road between Cape Town and Wymberg. From Salt River the same poles that carry the frontier wire will support the Simon's Bay line. The contractors' assistant, Mr. Holsboer, is about to leave for Port Elizabeth, to repair the Graham's Town and Port Elizabeth telegraph.* Upon the completion of these repairs, the King William's Town and East London line will be placed again in working order, after which the contractor will proceed to Natal to construct the line between Durban and Maritzburg, a contract having been entered into between the Natal Government and Mr. Wollaston, on behalf of the Company, securing a subsidy, payable for a number of years, upon the same principle as the contract for the Graham's Town and Cape Town line. There is every probability of the Natal and Cape Governments, aided by Her Majesty's High Commissioner, agreeing upon terms with the same parties for the extension of the telegraph from its present terminus (Graham's Town) to King William's Town, there uniting with the East London line, and from thence, through Kaffirland, to Natal. We shall then be able to communicate by telegraph with the seat of Government and the principal seaports of all the British colonies in South Africa, an advantage which cannot fail to be of immense value both to the Home and Colonial Governments, and to the commercial community generally. The manner in which the Telegraph Company are doing their work is universally applauded.

* Erected before Messrs. Siemens, Halske, & Co. took the contract for the construction of the new lines and repair of these old ones.

CORRESPONDENCE.

PRACTICAL TELEGRAPHY.

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—While reading a valuable work, recently published by Mr. R. S. Culley, which contains a great amount of useful information to those engaged and interested in telegraphy, it struck me that were you to devote a portion of your Journal to the diffusion of information founded on experience, you would be conferring a boon upon the telegraph service generally. A medium for the free interchange of ideas among those engaged in telegraphy has long been a necessity. Improvements tending to facilitate and lighten our labours can by such means be made known to the advantage of all; and the great number of youths now engaged in telegraphy will derive much useful information from the contributions of those more advanced in the knowledge of electrical laws and the management of instruments, &c.

J. EASTNOR.

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—It is with the greatest pleasure I hail the boon that is about to be offered to the telegraphic world, in the form of a periodical devoted to its interest. Perhaps I may be pardoned for offering a few remarks on a point which is of the utmost importance to us telegraph clerks. It is now getting a bye-word among several classes that on the whole English clerks are a "set of lazy fellows," &c. &c., while the continental ones are well up and versed in the science of telegraphy. Why is this? Let us take an example. Two men are set to accomplish a certain work; one has an abundance of books, has a paper that gives him continual instruction how to proceed, and has plenty of instructions to do it. Now let us see the other: he has neither the books, paper, encouragement, nor any one who will take the slightest trouble to give him the least instruction. We would of course naturally say, that the former should do it the best and first. So I maintain it is with the clerks of this country, when compared with those of the continent—one has everything, the other nothing. Therefore, I do not see why the English telegraph clerks should have their characters stained by the words of those who are in ignorance of the cause that brings the effect attributed to them. But now, while there is a prospect of a journal which has for its object the promotion of telegraphic interest, we may expect better things; at the same time I sincerely hope that the promoters will not forget that there are such persons as clerks in the telegraph service, and that the matter which is interesting to the telegraph engineers and electricians will be quite the contrary to a clerk. They require to be brought to it gradually. I should propose that a column or two should be devoted to the explanation of instruments, relays, batteries, &c., and written in such a manner as to interest the readers. I know that your paper is looked forward to with considerable interest, and if you possibly could make a portion of your paper interesting to the above class, you would not only have the good will of almost all the clerks, but you would have your circulation doubled.

But the space of your paper is valuable, and I should not like to exclude far more interesting matter. I will but just ask of you to place these matters under your consideration.—I am, Sir, your obedient servant,

Liverpool. J. R. O.

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—I shall be rejoiced at the appearance of the "Telegraphic Journal," if it only fulfil the expectations its title is likely to raise.

By all means let it be a "Telegraphic Journal," and not a miscellany of the sciences, "social" included. It is a want greatly felt, and there is none more competent to supply it than yourself.

Be assured there will be no lack of support. A paper devoted to telegraphic interests is evidently much needed, and, therefore, if it turn out a true representative of that interest, it will be appreciated in the most satisfactory manner.

The figures that are frequently published, purporting to give the amount of capital invested in this vast enterprize, and the number of persons employed, afford but an inadequate idea of either the one or the other. If, however, the new journal is conducted anything like, and is really made the exponent of the large, influential, and highly cultivated class engaged in telegraphic operations, you will soon have something approaching to occular demonstration of the multitude so engaged by the number of copies you will have to prepare weekly.

The "Telegraphic Journal" should be as welcome to the humblest clerk—aye, even porter—as to the gentlemen directors themselves, and, moreover, should be as indispensable to the ordinary shareholder as to the engineer and manufacturer; but to be of this cosmopolitan description will doubtless require earnest and close thought, incessant study, talent of no ordinary character, and a mind capable of taking a comprehensive survey of this vast science in all its multifarious and important details; add to which a thoroughly intimate acquaintance with every phase of the class or classes for which you write. Of this, however, you are doubtless more fully aware than I can possibly pretend to be, and, therefore, it might safely be passed over. Still, when one is desirous a thing should succeed, one is apt to be pretty free in dwelling upon various points, which, although not likely to be lost sight of in one sense, are nevertheless apt to make one nervous, lest all the time their prominent self-evidentness, being so constantly uppermost, should lead to a depreciated estimate, and this chiefly by virtue of their extreme familiarity.

You will pardon my free way of writing, but I feel satisfied that success depends upon the manner in which the journal is conducted and its general getting up. It is hardly fair to complain of a want of support if the journal does not as a whole contain that which is interesting to those who are expected to purchase it.

There are various grades, as I may call them, to cater for, not one of which you can with impunity ignore the existence of. Nor yet, again, will it be wise to be lavish towards one class at the expense of the other. The large number of amateurs who will seek instruction from your columns will not be so unreasonable as to expect more than a fair share of attention. They will, of course, be prepared to meet with a great deal in your pages which is beyond their comprehension, but this will doubtless only excite them to emulate the knowledge of those so far a-head; but what little space is devoted to them should be couched in language to be easily understood. The deplorable state of electrical nomenclature, and the way eminent individuals are at loggerheads with one another as to the applicability of certain words as denoting certain phenomena is a great drawback to the student in the acquirement of telegraphic knowledge. I, in concert with a great many others, am anxious that this state of things should cease, and trust your journal will be the means of setting many controverted points at rest; but this is only a hint by the way.

Of course the "Telegraphic Journal," as its title would seem to indicate, will be a scientific journal, not in the latitudinarian sense, but only so far as electric and telegraphic sciences are concerned; and in this respect I cannot but hope most earnestly that it will prove itself a text book, and never failing source of the purest description, to which the most advanced electrician will be able to turn to his advantage, conscious of finding at all times something that is worthy to be added to his store of knowledge. But while it should be a scientific journal of pre-eminent standing, in so far as it should be the *ultima thule* of electric and telegraphic knowledge, and its editor, justified by virtue of his superior attainments, in giving *ex cathedra* utterances, still it will doubtless be desirable that its pages should not be too exclusively scientific; indeed it becomes a query whether it should even have any considerable portion of its space taken up every issue with purely scientific matters. There is a large class mixed up and intimately interested in telegraphic affairs in a commercial sense only, and it is no depreciatory way of speaking to say, that a great number of these gentlemen are in blissful ignorance of the reconditics of telegraphic science and the mysteries of electrical theories; and in cases where tolerable acquirements have been made, it is more than probable that it is not made a subject of systematic study. To this class, therefore, a journal overcharged with a difficult subject, and withal uninteresting to them, runs the risk of being thrown on one side unread; and if that occurs a time or two, the question presents itself to them in this form, "Where is the use of my taking a paper which I do not or cannot read?" People of this description take a paper gladly if they can only be sure of finding in it the information in which they are interested. You, sir, know the class to which I refer and the information that will be suitable. News is an important element; do not, above all things, forget the news. Excuse my prolixity. I have been trying to show to you how the "Telegraphic Journal" may be made a success. I hope I have succeeded. Surely everything is propitious. The want exists, and you step forward to supply it. Do it faithfully and to the best of your ability, and sure I am that the eminent and enterprising firm which has undertaken the publishing will never have occasion to regret the step they have taken.—Yours obediently,

Croydon, Dec. 28, 1863. R. W.

[We thank our esteemed correspondent for his suggestions.—ED., T. J.]

TELEGRAPHY AND H.M. GOVERNMENT.

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—Judging from past and present appearances we have but too much reason to fear that no very important line of submarine telegraphs will be constructed unless Government assistance in some form is vouchsafed to that end. So far as connecting the colonies to the mother country is concerned, the Executive will not fail to see that this is effected, supposing no independent company is organized in the meantime that will forestall them. But we shall be safe in concluding that these things will remain in *statu quo* until it is seen how the cable turns out that is now on its way to the Persian Gulf. If this should prove a success—and we see no reason why it should not—it will give a great stimulus to telegraphic enterprize, but as surely no greater than is required, since every other project languishes from sheer inanition.

The world has gone by extremes, we may suppose, ever since man succeeded to the inheritance down to the present moment. The contrast between the nervous timidity of the present time and the overweening assurance and self-confidence of five years or so ago is as remarkable as it is regretable.

Then schemes were rife which were to encompass the whole earth—east, west, north, and south—with a perfect network of electric communication; the Atlantic was to be regularly zig-zagged with telegraphic cables, and everybody believed not only in their possibility but in their immediate execution. No misgiving had been manifested, and every isle in the Pacific might literally be tacked to our sea-girt shores, and kept there by as mysterious a bond as that which holds the satellites of Jupiter; and we should not only not have said it is impossible, but that it *should be*, and that speedily, although it should have transfixed us with amazement.

Now, however, we creep, and hardly creep, with an excess of caution almost ludicrous. The construction of a few miles of cable is esteemed a far more formidable business than the manufacture of two thousand miles was half a decade since. And when made in the most perfect fashion and passed the rubicon of severe tests which are supposed to represent the grossest aquæan circumstances it will be subjected to, it is finally submerged in something like that unsatisfactory bewilderment which a colossal unknown is supposed to produce, and which cannot be more aptly expressed than as "taking a leap in the dark."

The Government, too, indulges in the same excessive caution, and truly not without a cause. A burnt child ought to dread the fire; but experience should teach the juvenile that caloric is a useful agent in the economy of the world for all that, and, moreover, should reflect in what measure he himself was to blame for the unpleasant results. If the children of this world prove themselves to be wiser in their generation than the children of Downing-street light, the latter are surely capable of profiting by experience, without having recourse to the undignified proceeding of abjuring all similar connexions for the future, and withal should not omit to take stock of their own fair share of the blame.

The indisposition of the Government to assist in the accomplishment of projected lines is a serious drawback to submarine telegraph development. The thing is literally at a stand. The signs of life that are shown are more like the spasmodic action of automata than real life; and yet a little help judiciously held out would be of incalculable advantage, and would result in a measure of success that would amply repay the advances made. All this is more than borne out in the instance of the Atlantic cable. If Government would step forward with ever so little effectual countenance and aid, it is beyond a doubt that a very short time, comparatively speaking, would see this country in direct electric communication with the vast American Continent. As it is, however, a grand enterprize, nobly and heroically begun, sticks half way, and is in danger of coming to nought, or its consummation postponed for an indefinite period, for want of that patronage and aid which might be granted without the donors being any the worse, even in the case of failure; but, seeing that success is certain, it is surely impolitic to withhold that, the bestowment of which would meet with universal approval. This is not the worst, however; the fact of its being blown cold on in such a quarter prevents that spontaneous flow of sympathy and effectual assistance which others would feel disposed to accord. This coldness and indifference is interpreted as an entire mistrust of the whole affair.

Effectual but judicious aid in submarine telegraph extension is just that appropriation of public money, which, as it would be certain to meet with a good return, and moreover forward the noblest of enterprizes, would necessarily be countenanced by that public who provide the Executive so munificently. This is a matter that should be well looked after in Parliament. I much fear that telegraph interests are but inadequately represented there, and, therefore, hope to see the whole subject taken up in your columns from time to time, in order that the duties and obligations of Government may be exactly defined and enforced. Surely, it is high time that the present state of apathetic languor were superseded by rational activity. Of the two extremes this is by far the worse, for it is in a great measure unjustifiable, seeing the great advance that has been made in the science of telegraphy. As far as is possible for the most efficient and elaborate experiments to demonstrate, and, moreover, experience on a small scale, the success of properly constructed telegraph cables is a certainty, about which there cannot possibly be the smallest matter of doubt. It is a thousand pities, therefore, that this noblest of all enterprizes should languish mainly because a nervous timidity is oddly enough in alliance with a petty parsimony.

E. F. G.

TELEGRAPHIC NEWS.

THE ELECTRIC AND INTERNATIONAL TELEGRAPH COMPANY.—There are two vacancies on the Board of Directors of this Company, by the demise of Thomas Critchley, Esq., and the appointment of Sir John L. M. Lawrence, Bart., G.C.B., to the Governor-Generalship of India.

THE ELECTRIC TELEGRAPH AT THE KENSINGTON MUSEUM.—Several sets of instruments (Wheatstone's) are employed at this important national establishment, as a means of communication between its various departments. The large amount of private and public property exhibited from time to time within the building, rendered it necessary that the most effectual precautions should be adopted for its protection. The system of telegraphic communication is so arranged, that, in case of a robbery being discovered, an instantaneous notice can be given to prevent all egress from the building until a rigid search is made. This ingenious application of electro-telegraphy has relieved the establishment of a considerable amount of anxiety as to the security of the valuable property contained within its walls.

DURING the late severe gales the lines of the Bonelli Telegraph Company between Liverpool and Manchester, suffered serious damage, the two masts at Runcorn Gap being broken and the cable, that crosses the Mersey at this point, carried away. It was, however, secured and submerged, and is now in good condition, but owing to the length of damaged land line still in the hands of the engineer for repair and the large increase of business, rendering it necessary for the Company to open much larger premises in Manchester, the traffic has been temporarily suspended and the offices closed.

TELEGRAPH CLERKS' PROVIDENT FUND.—We learn with satisfaction that the above promising and important institution continues to gain strength by increased patronage and number of members, which now exceeds sixty. The yearly subscriptions amount to £51 18s. 6d., and donations £172 15s., or a total of £224 13s. 6d. Mr. Sheward, the chairman of the fund, who is a member of the Royal College of Surgeons, has kindly agreed to grant certificates free to every member. The Electric and International Telegraph Company's Dramatic Club intend to give a representation, for the benefit of the Provident Fund, early in the month of February.

Mr. L. W. COURTENAY, the able secretary to the Submarine Telegraph Company, has left that company, and entered the service of the Government Telegraph to India, taking charge, we understand, at Constantinople, whither he has already proceeded, to bear part in the preliminary operations necessary to formally complete the requisite arrangements for establishing and carrying on the important system of communication with India, to be inaugurated on the successful submersion of the Persian Gulf cable. Mr. Courtenay has been identified with the system of submarine telegraphy from its infancy. He was secretary to the Société de Mauley et Compagnie, which laid the first metal-coated submarine telegraph cable between England and France, and which, therefore, may be said to have been the parent and forerunner of the magnificent system of continental and insular communication since established. Mr. Courtenay was also the secretary of the Chartered Company that established telegraphic communication between England and Belgium, England and Hanover, England and Denmark, France and the Channel Islands, and subsequently again between England and Boulogne and Dieppe. Perhaps no gentleman possessed a more intimate knowledge of the various Conventions, concluded at different times, between the States of the Continent, for the regulation of telegraphic intercourse, and also of the agreements and working arrangements subsisting between this country and the various Governments of Europe, with most of which, indeed, Mr. Courtenay had had something to do. The Submarine Telegraph Company carried out, during Mr. Courtenay's tenure of office, successive reductions of tariff, which have contributed very greatly to the extension and permanent establishment of the submarine electric telegraph as an absolute necessity to the mercantile and general public. The late secretary was generally esteemed for his courtesy and for his business acquirements; and we think that all our readers who are acquainted with the gentleman of whom we are speaking will join with us in thinking that the Submarine Telegraph Company have lost, and the Government have secured, an experienced and valuable servant. The directors of the Submarine Telegraph Company, on Mr. Courtenay's quitting their service, presented him with a valuable gold watch and chain, bearing an inscription expressing their satisfaction with his long and efficient services, which extended over a period, as we are informed, of some thirteen years.

THE GREAT INDIAN TELEGRAPH.—A telegraphic convention has been recently signed between the Porte and the Persian government, on the basis of the convention of Brussels, which governs the whole of the international telegraphic regulations throughout the different states in which the telegraph system has hitherto been adopted. Mirza Hussein Khan, the Persian Minister at Constantinople, who was to leave for Teheran, will take this convention with him for final ratification by the Shah. It will prove of great advantage to the new line of Indian telegraphs, carried out under the supervision of Lieutenant-Colonel Stewart. In addition to the submarine cables from Bassorah to Bushire, and thence to Kurrachee, the telegraphic land wire will be prolonged from Bagdad to Hanokhan, on the Persian frontier, by the Turkish government, and will be carried on by the Persian authorities to Teheran and Schiraz, and thence to Bushire. The correspondent of the *Times*, at Constantinople, writing on this subject in its stages, in a late number of that journal, states that it is proposed ultimately to extend this land wire through Beloochistan to Kurrachee, and thus to secure uninterrupted communication in case of accidents to the submarine line. After the signature of the convention, a grand dinner was given in honour of the Persian Minister, Mirza Hussein Khan, at which most of the grandees of the Porte were present. The general treaty on the Brussels basis binds only the Persian government with respect to the transmission of messages to Europe. In Asia they have a separate arrangement with the Porte, by which the charge for telegraph messages is fixed at 20 para a league for 20 words. The Persian and English governments are drawing up a special convention on this subject at Teheran.

WEST INDIA ISLANDS.—An offer has been made to connect the whole of the West India Islands by telegraph with the main land at Cayenne, in French Guiana, and Key West, near Florida, if a grant of 6 per cent. on the toll can be obtained. The cost is estimated at £300,000.

SUBMARINE CABLE FOR THE ITALIAN GOVERNMENT.—A submarine cable for the above government is now in course of manufacture at the works of Mr. W. T. Henley, North Woolwich. It is to be submerged between Ottrante and Avalona, and is sixty-two miles in length. We shall in our next number give a full description of the cable.

AMERICAN TELEGRAPHY.—President Lincoln, in his Message to the House of Representatives, recommends to their favourable consideration the subject of an international telegraph across the Atlantic Ocean, and also of a telegraph between the capital and the national forts along the seaboard and the Gulf of Mexico. Such communications, established with any reasonable outlay, would be economical as well as effective aids to the diplomatic, military, and naval service.

La France announces, from St. Petersburg, that a telegraphic line from Eastern Siberia to Pekin has been agreed on by the Russian and Chinese governments, and that a series of block houses is to be conceded to the Czar along the whole extent of the wires, for their protection within Chinese territory, up to the very gates of the celestial city.—*Manchester Guardian.*

MISCELLANEA.

WE are not generally in the habit of considering attentively how intensely cold is space—that the diffusion of heat is only terrestrial, and for a short distance its average diminution, with height, being about one degree for each hundred yards, or sixty degrees for six miles (in round numbers, as an approximation not in excess of observed facts). We look at the sun, feel his apparent warmth, and with difficulty realise the conviction, that by going towards him—our great luminary, visible centre of our system—we should be frozen. What are heat, light, and electricity—three words for, perhaps, only one power or influence, under various forms or conditions—intimately correlated? All-pervading, ubiquitous, incomprehensible now to man, almost infinite in power, rapidity, and extent, though but an agent of the Almighty. Marvellous, indeed, are the effects of this subordinate influence as studied in these forms, and in other combinations, such as magnetism and gravitation. They indicate the power of Divine will looming through the mist of man's materialistic philosophy.—*Admiral Fitz Roy.*

THE PROGRESS of electro-telegraphy during the last twenty years presents a remarkable instance of what can be effected by scientific skill and commercial enterprise in so brief a period. The short experimental wire erected between Paddington and Slough, where, at the former station, the infant Ariel was exhibited on the sight-seeing Easter holidays at "one shilling each person," bids fair to girdle the earth, and Ariel's sway to assume gigantic proportions. The public, through the medium of the daily press, were recently informed that our lightning messenger left San Francisco, on the shores of the Pacific, on a certain day, and after having passed along some 4,000 miles of wire, deposited his despatch on board a swift steamer, which occupied nine and a half days in traversing the Atlantic ere it reached our shores, from whence the despatch was transmitted to St. Petersburg, on the Neva, the whole time occupied being ten and a half days, of which time Ariel occupied scarcely twenty-four hours—thus demonstrating that when an Atlantic cable is successfully laid St. Petersburg and the great telegraphic system of Russia reaching to the frontiers of China will be able to communicate with San Francisco and the British possessions in the Pacific in less than twenty-four hours. There are now no less than 10,000 telegraphic stations in Europe for the receipt and dispatch of messages. In India, 160. In Australia, viz., Queensland, 6; New South Wales, 35; Victoria, 44; South Australia, 21.

THE VELOCITY OF ELECTRICITY AND THE DURATION OF THE SPARK have been made the subject of elaborate experiments by M. R. Felici, who has inserted some notes thereon in the *Annales de Chimiè.* In his opinion, the best method of measuring the velocity of electricity is the observation of the sparks which arise at the interruption of an uncovered conducting-wire freely suspended in the air, and without an envelope of gutta-percha or silk, and traversed by the discharge of the Leyden jar. When we employ a battery and wires covered with gutta percha, and in the very variable condition of telegraph wires, causes of error are introduced, as has been demonstrated, principally by Professor Faraday. M. Felici also expresses his doubts as to the propriety of employing for this purpose the galvanometer or the electro-magnet. In a memoir lately published, he stated that by his apparatus he had determined the velocity of electricity to be, in round numbers, about 260,000 kilometres a second. Since then he has had new and improved apparatus made, which he describes in detail. With regard to the duration of the spark, he observed in his experiments a phenomenon already noticed by Professor Wheatstone and M. Feddersen, viz., that when the spark has a sensible duration it is composed of several sparks of an intensity successively more feeble and separated in themselves by infinitely small intervals of time. There is, consequently, one whole spark and some partial sparks of exceedingly small duration. According to M. Felici, the duration of the spark depends on the relation between the tension and the quantity of the charge. By augmenting the tension and diminishing the charge, the duration of the spark is also diminished. The duration of the spark, he says, also depends on the state of the surface of the metallic balls or points.

HEAT.—M. Stefan has communicated to the Vienna Academy some mathematical researches on the propagation of heat, and considers that the results he has obtained justifies the proposition "that heat propagates itself by radiation with the rapidity of light, by transmission with the rapidity of sound."

THE ROYAL SOCIETY.—At the anniversary meeting of this Society, Major-General Sabine, president, in the chair, the following officers were elected to serve for the ensuing year:—President, Major-General Edward Sabine, R.A., D.C.L., LL.D. Treasurer, William Allen Miller, M.D., LL.D. Secretaries, William Sharpey, M.D., LL.D.; George Gabriel Stokes, Esq., M.A., D.C.L. Foreign Secretary, Professor William Hallows Miller, M.A. Other Members of the Council, *James Alderson, M.D.; *George Busk, Esq., Sec. L.S.; *Col. Sir George Everest, C.B.; *Hugh Falconer, M.A., M.D.; *John Hall Gladstone, Esq., Ph.D.; Joseph Dalton Hooker, M.D.; *Henry Bence Jones, M.A., M.D.; Professor James Clerk Maxwell, M.A.; *Professor William Pole, C.E.; Archibald Smith, Esq., M.A.; Professor Henry J. Stephen Smith, M.A.; *The Earl Stanhope, P.S.A., D.C.L.; Professor James Joseph Sylvester, M.A.; *Thomas Watson, M.D., D.C.L.; Professor Charles Wheatstone, D.C.L.; Rev. Professor Robert Willis, M.A. The Fellows whose names are preceded with an (*) were not Members of the last Council. The President delivered his anniversary address. The Copley medal was awarded to the Rev. Professor Sedgwick for his geological discoveries, extending over a period of forty years. A royal medal was presented to the Rev. M. J. Berkeley for his contributions to botanical sciences, and especially to fungology. The other royal medal was awarded to Mr. J. P. Gassiot for his researches in electricity.

THE WONDERS OF THE WIRE.—The French Emperor's speech on the opening of the Session consisted of 2,044 words. The transmission by telegraph from the central station at Paris commenced as soon as it was ascertained that the reading had been completed, which was at about half-past one. The average time occupied in transmission to the principal cities of France and Europe was an hour and a quarter, or at the rate of 28 words per minute. The capitals for which the longest time was required, from the want of a direct communication, were Rome, St. Petersburg, Athens, and Lisbon. The speech was nevertheless received everywhere before the evening, and the journals of the whole of Europe produced it on the following morning the same as those of Paris.

PEAT.—A PROPOSED NEW INSULATOR.—The deposit of peat in Great Britain and Ireland occupy an area of not less than 6,000,000 acres, chiefly composed of vegetable matter (fir and pitch trees). It is impervious to water when manufactured in solid cakes—112 lbs. of *hydro-carbon* or peat grease is drawn from one ton of peat (used for lubrication, &c.) There are other and novel applications of peat that will give incalculable value to an article which has often been considered worse than useless in this country, and the supply of which is boundless. By passing the peat through a conical strainer it is immediately converted from rude lumps of fibrous mud into a homogeneous mass of the consistency of putty or dough. By placing a similar strainer, with smaller and more numerous perforations, directly under the other, letting the vermicular peat drop from the upper strainer into this lower one, and working the two strainers simultaneously, the peat is so perfectly tempered that it can be moulded into the most delicate forms, forming a substitute for wood, ivory or bone, gutta percha, clay, or plaster of Paris, in the manufacture of an immense number of articles. Its specific gravity is thus raised to 1·25, and its density and strength are so great that it may be applied to some purposes for which stones or iron is now employed. The twice-strained peat has all the appearance of ebony, and when rubbed it acquires a beautiful lustre.

EXPERIMENTS MADE FOR ESTIMATING THE TEMPERATURE OF THE SEA AT VARIOUS DEPTHS.—In latitude 24° 40′ S. the heat of the air was 72° 5′, of the water at the surface 70°, and of water at the depth of eighty fathoms 68°; August 27, 1772. Latitude 58° 21′ S. the heat of the air was 31° 5′, of the water at the surface 32°, and of water from the depth of 160 fathoms 33° 5′; December 27, 1772. Latitude 80° 30′ N. the heat of the air was 32°, of the water at the surface 36°, and of water fetched up from the depth of sixty fathoms, under the ice, 39°; August 4, 1773. Latitude 75° N. the heat of the air was 66° 5′, of the water at the surface 55°, and of water at the depth of 683 fathoms 40°; September 4, 1773. Sir James Ross, upon being examined before the late submarine telegraph committee, gives a very interesting account of the experiments made by him with regard to the temperature of the sea in southern regions. Sir James states that the results were symmetrical, and followed a clearly established law, which he explains as follows:—"During the many thousand years that the earth has revolved on its present axis, the ocean has been absorbing heat from the sun, especially at the equator, where its rays are most powerful. There the temperature of the surface of the sea at the present time is about 80°; this temperature diminishes very rapidly in descending below the surface of the few hundred fathoms, and then very slowly to a great depth. Thus—

The surface temperature is			80° 0′
At 150	fathoms below	the surface	54° 0′
300	do.	do.	46° 0′
450	do.	do.	44° 0′
600	do.	do.	42° 8′
750	do.	do.	41° 4′
900	do.	do.	40° 8′
1200	do.	do.	40° 0′
1500	do.	do.	39° 5′
1950	do.	do.	39° 5′
2100	do.	do.	39° 5′

This temperature of 39° 5′, Sir James believes, continues to the greatest depth, and which he calls the normal temperature of the ocean.

PRINTING BY TELEGRAPH.—Some interesting experiments with printing inks have just taken place at Miss Faithfull's printing establishment, the object being to test the utility of ordinary printing in telegraphy. An Italian gentleman has invented a process of printing by telegraphy which appears to take less than half the present time of transmitting a message. Every kind of printing ink have had their trial, some with very good success. The specimen printed by the process, transmitted from Liverpool to London, is before us, and appears completely successful. The Lord's Prayer, composed and printed at Miss Faithfull's office, and forwarded to Liverpool, is stated to have taken nearly two minutes and a half.

THE comparative electromotive force and liquid resistance of various forms of battery used in telegraphy, as determined by experiments by Captain Shaw, R.E., and Lieutenant Fowler, R.E., are as follows, in miles of resistance of No. 16 pure copper wire:—

	T.	L.
Graphite battery, plates 6′ × 2″	4·56	·38
Ditto in action for two days	4·96	·63
Muirhead's Daniel's plates, 4′ × 2″ and 4′ × 3″	4·36	·85
Ditto (greased cells) ditto	4·34	1·24
Chatham battery, plates 4′ × 1″, cast zinc	4·25	·84
Sand battery, plates $3\frac{1}{2} \times 4\frac{1}{2}$, freshly made up	4·56	·53

[T., the electromotive force or tension; L., the liquid resistance, or resistance to the passage of the current of electricity from the zinc to the copper.] The liquid resistance vary with the sizes and arrangements of the metals opposed to each other in the batteries, but will always be greatest, *cæteris paribus*, in those which require porous cells; hence the reason will be apparent why the force circulated by the small battery used for the R.E. telegraphs is equal to that derived from the large Muirhead's battery with the porous cells.

TELEGRAPH IN COCHIN CHINA.—A fact worthy of remark is, that, at the commencement of the insurrection, the rebellious Annamites left our lines of telegraph intact, a circumstance which can only be explained by the ignorance in which they were regarding their purpose, and the power which the telegraph added to our means of action; we have seen how, by means of it, the military authority had been able, from the 17th December, to give the alarm; it rendered it possible to follow day by day, and hour by hour, the progress of the insurrection, and to send reinforcements to the points most menaced. During the attack on the fort of Long-than, situated on the route from Bien-hoa to Baria, the superior commandant of the province, installed in the bureau at Baria, at a distance of forty kilomètres, directed the defence, and prescribed the sorties, according to the information (renseignements) he received. But the facilities resulting from the preservation of the telegraph were not left to us until the end, and, in the first days of January, 1863, the Annamites, better informed, broke the precious instruments which, until then, they had despised; 100 kilomètres of the lines were destroyed, especially those from Long-than to Baria, and from Cholen to Mytho, in places (centres) which had not been completely explored, and where numerous (beaucoup de) bands had sought refuge. It was necessary to await the re-establishment of peace, to repair the injury, but, wherever the lines were left intact, the telegraph remained until the end, a useful auxiliary to the government of the colony. The Administration of Marine, in proposing for the decoration of the legion of honour, the chief of the mission, believed it due to render a special testimony to the assistance which the telegraphic service had lent it:—"The Vice-Admiral, governor and commander-in-chief in Cochin China," said the Minister of Marine, "has informed me, that, in spite of numerous difficulties, the *personnel* of the telegraphic lines had attained, during the course of the year 1862, the completion—with the exception of the line from Baria to Cape Saint Jacques—of the great principal net-work of electric communication in lower Cochin China, as well as the establishment of some of the branch stations (succursales). In pointing out to my attention, the zeal and intelligent devotion, of which the *employés* of the telegraphic service have not ceased to give proofs since their arrival, the Vice-Admiral Bonard recommends, in a most special manner, M. Hudot, director of transmissions, chief of this important service, whom he proposes for the Cross of the Legion of Honour."

RECENT PATENTS.

963. R. KNIGHT, Dunkirk, France, "Treating and preparing iron, copper, and other wires for telegraphic and other uses, for the purpose of preventing them from corrosion or decay."—Dated 17th April, 1863.

The patentee claims treating and preparing iron, copper, and other wires for telegraphic and other uses by coating such wires with pure tin, and condensing the same thereon by any suitable mechanical means, as described, for the purpose of compressing or condensing the coating of tin when applied on the surface of metallic wire, in order to so completely close up the pores of the tin as to prevent the coated wire from being chemically acted upon by acid or other solutions, or from the oxygen of the atmosphere, or from other atmospheric, gaseous, aquæous or submarine influences.

A. BROOMAN, Fleet-street, London, "Laying submarine telegraph cables in communication." Dated 13th May, 1863.

This invention consists in connecting to the cables as they leave the vessel from which they are paid out, buoys filled as hereafter is explained, and which after a certain time lose their buoying properties, whereby a nearly consistent tension is maintained on the cable. In addition to the buoys, in some cases heavy weights are attached, and cause the cable to descend to the bottom of the water in which it is being submerged. The buoys are by preference in the form of balloons of caoutchouc or waterproof cloth, and when not extended occupying but a little space in the vessel. These buoys are provided with a tap in which there are two ways, one for the admission of air and the other closed by wire gauze for the escape of air; the wire gauze is covered with gum, or other material which will dissolve after exposure to the water, and according to the nature and thickness of those coverings so will the air escape more or less quickly after the balloons have been submerged. The balloons are attached to a cord, the lower end of which carries a weight, and as the cable is leaving the vessel the balloons are attached by throwing and twisting the weighted end of the cord round it. Instead of balloons, or together with balloons, buoys in the form of parachutes may be attached to the cable in a similar manner to the balloons.

PRICES CURRENT OF INSULATING MATERIALS.

GUTTA PERCHA, AS IMPORTED.

Genuine mixed, first and second qualities.	2/3 to 2/6 per lb.
Good re-boiled	1/7 to 1/10 „

INDIA RUBBER.

TO CORRESPONDENTS.

SCOTTISH VULCANITE COMPANY *v.* BENDER.—A full report of this important trial will appear in our next number.

Communications intended for publication must be authenticated by the names and addresses of the writers; not neccessarily for insertion.

Letters relating to Advertisements are to be addressed to the Publishers. All other letters and communications to be addressed to the Editor of the *Telegraphic Journal*, 5, Suffolk-lane, Cannon-street, London, E.C.

The *Telegraphic Journal* can be had of all news-agents in town or country, and at the various railway stations; or, it can be supplied, if preferred, direct from the Office on the following terms (paid in advance):—

	s.	d.
Quarterly	4	4
Half-yearly	8	8
Yearly	17	4

Advertisements must be delivered to ensure insertion before SEVEN O'CLOCK on Wednesday evening in each week. The charges for Advertisements are—

	£.	s.	d.
Whole page	4	4	0
Half ditto	2	10	0
Quarter ditto	1	7	6
Four lines and under (single column)	0	3	0

Single Advertisements from the country must be accompanied with stamps in payment.

The *Telegraphic Journal* is registered for transmission abroad.

PRACTICAL TELEGRAPHY.

PRACTICAL men are very apt to despise science, and think that theory and practice are diametrically opposed to one another. Nor are students entirely free from a similar failing; they are too apt to affect a superiority over practical men, to ignore the results they have arrived at, and to exclude such results from their works.

Almost every one who is engaged in telegraphy is a practical man; there are few who have studied the science of electricity; many who believe that "book-learning" is of no use; and, it must be confessed, that of the two, an imperfectly-educated practical man is far more useful than one who has a mere smattering of science; the first knows only what he has actually seen, the second may have seen nothing, and have learned nothing accurately from his books. What little the former knows is, as far as it goes, valuable; what the latter fancies he knows is, probably, worthless. The truly useful man is he who combines both theory and practice, who understands the reason why he acts, and can check his reasonings by his knowledge of actual results.

The starting of a second journal, principally devoted to the telegraph, gives us an opportunity of assuring our practical men that they would be benefited by studying theory. Let them look around them, and see who are filling the most important positions in the service. Are they not, firstly, those who, with a talent for business, and for placing themselves prominently before the public, possess also a thorough knowledge of the science of their profession; and, secondly, those who combine the knowledge of the theory, with experience in practice, but who are deficient in the pushing quality of the first. No man can rise to the first rank in any department of applied science, unless, indeed, he be a man of extraordinary genius—unless he combine science and art.

"Rule of thumb" is of no use in new circumstances. A merely practical man, who knows nothing but what he has seen with his own eyes, can scarcely divest himself of a prejudice in favour of what he has been accustomed to, and especially of what he used when all was fresh and wonderful to him. Thus men are to be found still, who consider nothing can be better than the old *cones* and *winders* of their early days; and who, in spite of the clearest evidence, still dislike *earth wires*. We well remember, also, that there was the greatest difficulty in introducing the printing system; the practical men stuck to their double needles. Yet who would now regret the change?

It may be strange that in an art not twenty years old there should be Conservatism, but nevertheless it is so, and there are many who detest novelties, not because of the trouble they have in comprehending them (for they are real practical men to whom a new instrument is a puzzle), but because they are *innovations*. Such men generally complain that they are badly paid, and desire that society, and things in general, shall be reformed and reconstituted.

Then, had there been no students, no scientific men, where would have been our progress; nay, where would have been the telegraph itself: it surely was not invented by our merely practical man.

But the men of science must also permit us to say that, had it not been for the men of practical observation and active work, there would have been but little improvement. Our books, if written by men of no experience, are apt to mislead. It is most difficult, perhaps impossible, to arrive at all the bearings of a subject by mere thought or reasoning, even if its broad general truth is confirmed by experiment; especially so in our science, in which the experiments are on too large a scale, and too costly to be performed in a laboratory.

Hence the great utility to us of the scientific practical man.

For example, it is stated in scientific works that, in order to produce the greatest possible effect with a given surface of metals in a battery, the sheets should be cut into so many pairs as would, if arranged to the best advantage, be exactly equal in resistance to the rest of the circuit.

Now, if a telegraph battery were constructed on this principle, it would be found to fail. Is the theoretical statement incorrect? By no means—it is perfectly true. But, firstly, we do not require the *greatest possible* strength of current, but a current strong enough *to give good signals;* secondly, we want a battery which shall last for some time, without growing feeble; and, thirdly, one which shall make up for the current lost by leakages on the line. Hence the practical arrangement differs widely from the theoretical, as usually stated, because the subject is not considered in all its bearings in the scientific works referred to, and the statement, as it stands, is eminently calculated to mislead the practical man.

The *merely* scientific man is, then, a worse guide than the merely practical man, and the due mixture of science and experience has produced, and will always produce, men of the first rank.

Practical men then, study the science of your art, and enter a *profession*, new indeed, but honourable.

SUBMARINE TELEGRAPHY AS AN ENTERPRISE.

To say that Submarine Telegraphy is the greatest enterprise of the age, is to use a hackneyed phrase, which has now passed into a truism, and which, like a great many other indubitable hypotheses, runs the risk of becoming meaningless from frequency of repetition. It is a large expression nevertheless, and yet it may be rendered still more superlative, by insisting that it is not only the greatest enterprise of the age, but that it surpasses all others on record in any age.

Our present object, however, is not to reiterate that which, perhaps, few will gainsay, but rather to show that, apart from this consideration, it is an enterprise which offers rare advantages to those who are in a position to throw themselves into it.

Judging, however, from its present condition, and the tardiness shown towards the object by those who could really forward the work if they chose, to no inconsiderable extent, it might appear, to a casual observer, as being indicative of just the opposite of what we assert.

Of course every true lover of progress, and ardent enthusiast after that desideratum which they know to be practicable, must sincerely deplore such a state of lukewarmness; but fortunately, the consciousness that this is one of the trying ordeals through which all great designs and projects must pass, affords some gleam of cheerful hope that the dawn cannot be far off, while

past experience will inculcate a salutary lesson, and tend to restrain impatience.

At this time it will not, perhaps, be inopportune to dwell briefly on two points with respect to submarine telegraphic enterprise: first, that it is a safe, because practicable undertaking; and secondly, that it offers by far the highest return on the capital invested.

As regards the safety of such projects, it resolves itself into the question of success or non-success in the manufacture and submergence of a cable. It is to be regretted that a vast deal of dubiousness exists upon these points, and not altogether without cause; this must be removed; be it ours, therefore, to use such humble means as we possess to that end.

We do not share in this mistrust: we believe in the certain and invariable success of the submarine telegraphy of the future, and that too, without feeling ourselves chargeable with presumption. We have such confidence in our cable manufacturers now, that we feel perfectly certain they are competent to produce efficient, not to say perfect cables; and even were there cause for misgiving on this point, certain we are that our electricians and engineers are too honest, too jealous of their reputation, and concerned too much for the public good, to allow a submarine telegraph cable to pass as perfect, which had failed to stand the numerous and searching tests which, happily, the advance of telegraphic science has brought into use for that purpose.

We feel perfectly safe, therefore, in assuming that a faulty cable will never be permitted to pass beyond the curriculum of any electrician worthy of the name, hence failure can hardly originate in that quarter.

But, it may be urged, the most perfect cable ever made may be irretrievably injured in the paying out, and certainly it would be difficult to say how much of past mishaps are attributable to this cause. This is by no means necessary, however, unless we irrationally assume that past contrivances to this end represent the *ne plus ultra* of wise arrangements and mechanical skill. It is quite conceivable that machinery may be constructed so exquisitely adapted for the purpose as that the cable should be comparatively unaffected by whatever description of weather or rough sea it met with during the process of submersion. For the past three or four years, perhaps, as much attention and careful study has been devoted to this important subject as to any point that concerns the all-important matter of submarine telegraphic success, and, we may safely say, with results equally happy, and equally creditable to those gentlemen who have laboured so diligently at the praiseworthy and self-imposed task. The effectual and safe submergence of ocean telegraph cables need not, therefore, excite the smallest apprehension: it is a difficulty virtually overcome, and we can but sincerely hope that those who have helped to conquer the difficulty may speedily reap the substantial reward they merit.

Humanly speaking, success in submarine telegraph enterprise is a certainty.

In this part of our subject, it only remains for us to speculate upon possible adverse circumstances, over which, probably, we may have no control. And here we would throw aside all vain confidence and presumption, in presence of that Supreme Power "who hath measured the waters in the hollow of His hand, and meted out the heavens with a span," and humbly acknowledge that if He wills to the contrary, our best efforts to annihilate time and space will be abortive. Nevertheless, we know of nothing, at present, that transpires in the great deep, such as natural convulsions, of whatever character, that warrant us in indulging in prognostications of failure consequent thereon.

The mystery which enshrouds the fathomless abysses of ocean is, of itself, apt to be construed into plausible arguments that submarine cables can never be looked upon other than as doubtful ventures, with the probabilty of non-success vastly preponderating; but, assuredly, this is frightening oneself with unsubstantial chimeras. To assert that the plateaus of the undiscovered ocean beds are inimical to the safe deposition of a telegraph cable is, at best, but a gratuitous assumption, and so, for the matter of that, is the contrary opinion; but, in these things, we can only reason by analogy, and a train of inductive reasoning from observed phenomena to supposed phenomena beyond our ken, will, indubitably, be more favourable to the latter hypothesis than the former.

Except in cases of gigantic convulsions, in which we may suppose whole continents sunk and others upheaved, and the physical conformation of vast portions of the globe utterly changed, we know of nothing that would lead us to infer that, beyond a moderately fathomable depth, there is aught to be met with but a state of absolute repose; and, since by gravitation all denser bodies ultimately find their way to the bottom, it is inconceivable that that bottom should be rugged and flinty. There may be unknown dangers, of which at present we have no conception, but it is more probable they exist only in the imagination of the timid, or are the speculations of fire-side philosophers.

We will consider the second part of this subject in our next.

MR. C. F. VARLEY'S TRANSLATING APPARATUS.

MR. VARLEY has recently published, in the form of a small pamphlet, a description of the above ingenious and useful apparatus, now extensively employed on the lines of the Electric and International Telegraph Company, to which the inventor has long acted as Chief Electrician. These instruments were first constructed for working the International Telegraph Company's Dutch Cables, in 1854, to overcome the effects of the induction. The construction of the instrument is fully explained by numerous diagrams. One of the great advantages obtained by the arrangement adopted, consists in the relay being self-adjusting, owing to the system of working by the reversal of battery currents; consequently, the variation of the strength of the currents, from humidity of the insulators, &c., seldom necessitates any alteration in the adjustment of the relays.

The apparatus consists of two complete sets of printing instruments, each composed of a Morse machine, two relays, a spacing apparatus, two switches, a galvanometer, and a key. The two sets are connected with each other in such a manner as that either may be used separately as a terminal instrument, or the two combined as a translating apparatus; an operation performed in half a second, on either station giving the signal, D F.

The Morse machine is nearly similar to those in ordinary use for printing circuits, consisting of a pair of rollers put in motion by clockwork, carrying the strip of paper between them. In the upper one is a groove, in which the style or embossing point of the moveable armature plays. Under the pallet of the armature are placed the coils of an electro-magnet. When a current is sent through the coils the armature is depressed at one end and raised at the other; the latter carrying the style embosses the paper as it is drawn forward by the rollers.

The relays—one used for closing the marking circuit, the other for closing the spacing circuit—are composed of a horizontal bar electro-magnet, which is moveable within its coils, which are ordinary cylindrical ones, separated into two parts to allow the axis of the bar to pass through; each end of the bar plays between the poles of a permanent horse-shoe magnet, each magnet being similarly placed in respect to its poles. When a current passes through the coils the moveable soft iron core is deflected to the one side or the other, according to the way in which it is magnetized. When the current which is intended to mark the paper is sent through the marking relay, the bar is deflected against a metallic point, which is in connection, as shown in the diagram, with the zinc pole of the local battery, the bar itself being connected to the copper pole. When on the passage of a current through the coil the bar is deflected as above, the local circuit is closed; the armatures on the levers of the Morse machine and spacing apparatus being simultaneously drawn down, as hereafter explained.

The spacing apparatus consists of an electro-magnetic coil, with an armature and pallet supported on an axis above it, and furnished with two pillars, with adjusting contact screws to limit its upward and downward motion.

The line switches are for the purpose of dividing the line, if necessary, so that the translating station can communicate with any station on the up or down line separately. This is accomplished when the switch handles are turned to the right (I Q). When in the other position, viz., to the left (D F), the keys are taken out of circuit, and both line wires are connected to the translators, so that the distant stations can communicate with each other.

When receiving a message, or translating, the handles of the key switches are placed to the right (*receive*); but when signals are required to be sent by the translating station, the handles must be turned to the left (*send*).

The galvanometers are provided with two separate coils of wire, so that the outgoing current, which is strong, may pass through only a short coil, and the receiving current, which is comparatively weak, through a longer one, thus making the galvanometer show the force of either current. The shorter coil may be cut out of circuit entirely by the insertion of a plug provided for that purpose.

The keys are used for the transmission of currents either way, when the line switches are at "I Q," and the key switches at "*send*."

The induction plates are composed of lead or carbon, charged with diluted sulphuric acid, and when once charged require no renewal; this solution does not evaporate. They give no current themselves, but are capable of receiving an induced charge. If a galvanometer be inserted in the circuit immediately after passing a current through them, a strong deflection will be observed; but this will gradually decrease in strength until it nearly disappears, the use of these are explained further on.

The whole apparatus may be worked from one main set of batteries, or separate sets may be employed if preferred. If the former plan be adopted, the batteries must be unequally divided; the copper pole of the larger or positive battery, and the zinc pole of the smaller or negative battery, must be led to the apparatus, the other poles being put to earth.

Assuming, then, that the up station is transmitting a current along the line, and also that the line switches are turned to the left (D F), in a position for translating, and let the current be a marking one (*i.e.* a positive current) coming from the up line it enters the shorter of the two separate coils of the galvanometer of No. 1 set, thence it goes to the line switch, from which it passes passively through the Morse machine and the spacing apparatus of No. 2 set, and back to the marking relay of No. 1 set, through the coil of which it passes; thence it goes through the coil of the spacing relay in a reverse direction, and finally passing through the longer coil of the galvanometer, it makes its escape to the earth.

In passing through the coil of the marking relay of No. 1 translator, the current deflects the armature, and closes the local circuit, which causes the armatures of the Morse machine and spacing apparatus to descend simultaneously. The armature lever of the Morse machine being connected, through the galvanometer and line switch, with the down line, and the pillar which limits the downward motion being connected to the copper pole of the relaying battery, when the armature descends a current is transmitted on to the down line, marking the paper at the distant station. During this time, although the armature of the spacing apparatus has been drawn down, it has sent no current; but when the armature of the Morse machine is released by the sending station reversing the line current, the spacing apparatus comes into play and transmits a current the reverse of that before sent by the Morse machine.

The local circuit is arranged thus:—When the armature of the marking relay is deflected, the current from the local battery passes through the coil of the Morse machine and that of the spacing apparatus, and through the induction plates. On its arrival at the latter it is divided, one portion going through the coil of the spacing apparatus, and the other portion through the induction plates, which are placed in a loop on the coils of this part of the translator. When the distant station reverses the current, by allowing his key to ascend, the armature of the marking relay is deflected back to the non-conducting point, breaking the local circuit, in consequence of the line current traversing the coil in a contrary or reverse direction; but as the line current passes round the spacing relay in the opposite direction, the armature of this relay is now deflected, and permits the current from the local battery to pass through the coil of the spacing apparatus and the induction plates only, when the armature of the spacing apparatus only is depressed, while that of the Morse machine is elevated, connecting the down line to the zinc pole of the smaller battery. In this way reverse currents are translated from station to station.

The use of the induction plates is this:—When the local circuit is broken, the induced current from the leaden plates holds down the armature of the spacing apparatus for a short interval, and thus prevents it rising during the reversal of the current.

To recapitulate:—When a distant station transmits a marking current (copper, for instance), the armature of one of the relays is actuated, and the local current passes through the coil of the magnet of the Morse machine, and then divides itself between the coil of the spacing apparatus and the induction plates, the Morse machine transmitting a copper current on to the distant station. During this time the spacing apparatus is ready to perform its part in sending on a negative current, but cannot do so until the sending station reverses his key: this done, the armature of the spacing relay is then deflected, and allows the spacing apparatus to act alone, and transmit a zinc current. By the addition of the induction plates to the coil of the spacing apparatus the armature is kept down and in readiness to send the zinc current, instead of retiring at each break of the line current as it otherwise would do.

These instruments, at a station, are connected to a universal switch, called an "Umschalter," and thus, in less than two seconds of time, any two circuits can be linked together. This invention has considerably reduced the cost of transmitting messages across the country, and has, by reducing the number of hand transmissions, reduced the number of clerical errors, besides expediting the rate of transmission. For example:—a message between Windsor Castle, and Her Most Gracious Majesty's abode at Balmoral. The electric current from Windsor goes to York, and thence to earth; the York translator sends on a new current to Edinburgh, which goes to earth there; the Edinburgh translator sends on a third current to Aberdeen, and the latter station translates on a current to Balmoral, which station speaks as easily with Windsor Castle as if it were only twenty miles distant. Balmoral station is able, in the same way, to speak to Amsterdam, and there, by modification of the instrument, just described, the reversed current system of Mr. C. F. Varley, is translated into the single or ordinary Morse system, and *vice versâ*, the single current system of the Continent is most ingeniously made to call into play the reversed current system of Mr. Varley.

The operators in Great Britain do not perceive the break, nor do the telegraphists of the Continent know, except by book, that such a break exists as Amsterdam. The detail of this early and curious invention, necessary to meet a great public want, and to put all the vast continental network of telegraphs in direct communication, with the condensed, but extensive system of the great pioneer company, cannot be attempted on this occasion, and it would require considerable acquaintance with the subject, to enable the reader to follow the apparently complex, but, in reality, simple contrivance to overcome the difficulties which present themselves.

At the Manchester British Association meeting, that town was, during the great "Soirée Scientifique," put in direct communication with St. Petersburg, Odessa, Taganrog, on the Sea of Azof, and with the frontier of China, the transmission across 4,000 miles of wire occupying not more than two seconds of time.

MR. R. S. CULLEY'S NEW WORK.*

(*Continued from p.* 3.)

THE most interesting, if not the most important, branch of electrical science to the practical telegraphist is that of insulation, to the consideration of which Mr. Culley has devoted the fourth part of his book. The humidity of the atmosphere is the greatest enemy the telegraphist has to contend with. All the resources of the fertile minds of our most eminent electricians have been directed towards the mastery of the effects of moisture. It is easy to obtain materials which, in their powers of resistance, are sufficient to pro-

* A Handbook of Practical Telegraphy. By R. S. CULLEY, Telegraphic Engineer and Superintendent. London: Longman, Green, and Longman.

duce an effectual bar to the passage of the current from the conductor to the earth, but this power of resistance is immediately nullified on the first deposition of moisture on their surface. The earliest insulator practically applied was an ordinary goose-quill, but this was speedily found inoperative, and replaced by brown earthenware. Various shapes, rings, cones, umbrellas, *et hoc genus omne*, in this material and in glass, while porcelain, ebonite, &c., have been successively applied at various periods of our progress, and insulators, at first considered almost perfect, have been substituted for others still more perfect, and even now there is great room for improvement. An historical account of the various steps of the insulator would be extremely interesting, but Mr. Culley has carefully abstained from dealing with this branch of his subjects. He has contented himself with detailing the various obstacles to be surmounted, and the causes of failure and interference:—

The insulation of a line is never perfect, even in dry weather. There is a loss at every point of support, even when the insulators are clean, and this is considerably increased when their surfaces are damp, more especially so when dusty, dirty with smoke, or salt from being near the sea. When the wires are not galvanized, a slight coating of rust is formed upon the insulators by the rain dropping from the wires; this is very hurtful. The wires are often hung with spiders' webs, which, when covered with dirt and moisture, conduct; and on a long line the leakage from wire to wire through damp air cannot be altogether without effect. Though it may be extremely small at any given point—so small, indeed, that the tests hitherto made have failed to discover any conduction whatever—yet the total surface exposed is enormous, being as much as 220 square feet per mile of No. 8 wire. A very rough test will show how much insulation is affected by dirt or smoke, and too much care cannot be taken to keep the insulators clean.

As damp affects insulation so seriously, great care was taken in the earlier telegraphs to protect insulators from the rain by wooden roofs; but it has been found that such coverings are not only useless, but injurious. They do not themselves insulate, they afford no protection in fogs or continued rain, for then every part becomes equally damp. They harbour spiders, which spin their webs over and among the wires. They hinder the drying of the supports, and prevent the rain washing off the dust which covers the insulators. The inside of a hollow insulator, or that part which is protected by a wooden arm, is always dirtier than those parts which are fully exposed, and damp dirt conducts far better than a film of dew or clean rain water. Insulation is frequently improved by a heavy summer shower. There is a great disadvantage in placing insulators under bridges, where they are quickly covered with smoke, and are protected from the cleansing effect of rain. The umbrella-shaped insulator secures all the advantages of the roof in keeping an insulating surface dry in moderately wet weather, while it adds to its insulating power by increasing its length.

He has shown—though, perhaps, not in the most mathematical or elegant style—that surface, as was once considered, is not the most effectual means of improving the resisting powers of an insulator. As he remarks,—

The best insulator is that which has the smallest diameter, with the greatest length of surface between the wire and the bolt, or support. Length is most easily given by hollow or cup-shaped insulators placed inside each other.

The affinity of a material for moisture, or its power to attract damp, is an important point. Glass, though a better insulator than porcelain, becomes damp much sooner. If a glass tumbler and a teacup, each filled with cold water, be brought into a damp warm room, the glass will be covered with dew long before the porcelain shows any signs of moisture. The glass supports of apparatus used for experiments on frictional electricity must be varnished with shellac, to lessen this affinity for moisture.

Ebonite insulates much better than glass, and is far less apt to become damp than even porcelain. It is the best material yet known for insulation, but we have not had sufficient experience of its durability to judge of its power to bear exposure to the weather.

He has devoted considerable space to the investigation of the effect of leakage, or bad insulation at various points of the circuit, upon the received signals, and the effect of increasing the battery power by reducing the internal resistance of the battery, or adding to the number of cells upon the strength of the received current. He has by no means exhausted this branch of the science, and much remains to be written upon the ill effects of rain, fogs, and moisture in general, upon the insulation of our lines.

The philosophy of *Induction*, which is discanted upon in the fifth part, is more interesting to the submarine than to the land telegraphist; yet it is one which every practical man should thoroughly understand. Owing to the almost universal abandonment of underground wires of any considerable length its effects are rarely visible but on submarine lines; still, a knowledge of inductive effects assists immensely in the comprehension of numerous peculiar phenomena daily observed on circuits and in instruments. Induction is a very peculiar action, and requires great study to master. Experiment alone will lead to its thorough knowledge. Mr. Culley's remarks will, however, materially assist the student.

This part concludes with a short account of the disturbing effects of atmospheric electricity, and a description of that unaccountable and extraordinary phenomenon termed "Deflections:"—

"DEFLECTIONS," OR "EARTH CURRENTS."

Occasionally, especially during the aurora borealis, strong currents—sometimes steady, at other times changing their direction very rapidly—appear in the wires. These currents are not caused by atmospheric electricity, for they cease if a wire be disconnected at one of its ends, and they appear equally in buried as in suspended wires. They seem rather to be caused by currents flowing from one part of the earth to another, which enter the wires by one of their earth connections and leave them by the other, when the currents happen to be passing in that direction.

The wires are constantly traversed by these currents, but it is only at times that they attain sufficient force to affect the apparatus.

They appear most frequently, and have greatest power, on lines lying N.E. and S.W.; but it appears that the direction of the current changes with the hour of the day, so that one line may be more strongly "deflected" in the morning, another in the afternoon.

The current has frequently been seen to leave one circuit and to appear upon another previously free.

Communication may be kept open by the use of a magnet, to counteract the effect of the current. But when deflections are very strong and very variable in direction, the best method is to disconnect two wires from earth at both ends, and to use one as a *return wire* to the other in place of the earth.

(*To be continued.*)

TELEGRAPH PROPERTY.

(*Continued from p.* 5.)

THE tendency of the present day is decidedly to cheapen everything. Telegraphs and telegrams must consequently follow the general rule. Before, however, an article can be advisedly cheapened, there are two essentials. One is that the cost of manufacture be reduced, and the other that the consumption be proportionately increased. We may safely state that telegraph property falls within these two contingencies.

The manufacture, or rather the construction of telegraphs, has been considerably reduced in cost since their first introduction. The chief cause has been the expiration of the principal patents under which the original telegraphs were constructed, whilst the increase in the number of contractors for this description of work has, no doubt, assisted in the same direction. We believe we are within bounds in stating that work which used to be valued at £40 per mile would now be readily undertaken at little more than half that sum. The same reduction has also been experienced in the cost of the various descriptions of instruments. The heavy cost of the works to the older companies will, doubtless, find an adequate set-off in the comprehensive system which they have been enabled to establish during the existence of their patents, whilst, although the more recent companies will have the advantage of cheaper construction, they will have to make their lines and obtain their traffic in the face of existing competition.

Judging, however, from the official returns which were published in this journal last week, it is tolerably evident that a sufficient demand and inducement exists for increased means for telegraphing, and it is probable that the greater the facilities that are offered the more they will be appreciated.

We could not, however, for one moment suggest a reckless competition as to tariff; in such cases the public are temporarily benefited at the probable permanent cost of the telegraph companies.

The tariff for telegrams has, as a rule, been fixed on the mileage principle and in proportion to the capital expended. This was, no doubt, the correct basis, the probable amount of business between the various stations being also taken into consideration.

The preliminary cost of the construction of telegraphs having thus been reduced, and the natural progress of the period having led to an increased use of the telegraph, it is a necessary consequence that we must look forward to reduction in charges, which there is every reason to believe will be more than compensated by an increased number of messages.

(*To be continued.*)

TO ERECT A LINE OF TELEGRAPH.

In obedience to the wishes expressed in our last, we propose to give in a popular form such instructions as must prove of value to those who desire to obtain the requisite knowledge of practical telegraphic engineering. As the aspirant must commence with one branch at a time, the line, battery-room, machinist's shop, or steamboat (for submarine cable work), is each open to his choice, and, no doubt, he will first select the line, especially if he has hitherto been confined to the signals department, which has enabled him to become partially acquainted with the instrument and battery, their form or construction, and their use.

It is questionable whether, in first selecting the line, his choice will be as wise as it may be delightful, but he will find much to amuse as well as instruct him, and this being the case, he is more likely to follow up his employment since it is a means of affording him pleasure.

When an engineer starts to erect or lay out a line of telegraph, he is not always the pioneer. There is a difficulty in his way called the "way-leave," and as much depends upon this, some words must be passed upon it. When, as in the case of the large English telegraph companies, agreements are made with the railway companies, the bogey "way-leave" is settled mainly by the directors, the secretary, and their chief officer, L.S.D., Esq., and thus the engineer has nought but plain sailing. When the London and North Western Railway Company first established the telegraph system over their lines, they not only gave an exclusive right of way to the Electric Telegraph Company, but paid them handsomely for the railway telegraph to be erected for the partial use of the Railway Company. This was a "way-leave" worth having, for it gave the Telegraph Company a positive power to prevent others from occupying the same ground, and for more than five years London had but one line of communication to Birmingham, Liverpool, Glasgow, &c. It was in vain that the British Electric Telegraph Company, formed for working Highton's valuable patents, endeavoured to force their way over the London and North Western or other railways; they offered to pay a "way-leave," and do the telegraph work for nothing, but (and it is with the view of showing the importance and the difficulty in getting a right of way that this is mentioned), failing on every side, they, in August, 1851, decided upon applying to Parliament for both road and railway powers.

At the present day the railways are pretty generally occupied, and though some of the telegraph companies obtained compulsory road powers, and these were freely used by the British Telegraph Company, Parliament has now given general powers, under the Telegraph Bill of last Session, to every company having a special Act of Parliament, and thus this difficulty is (though by no means got over) set upon a decided footing. The Act is sufficiently explicit to render it unnecessary to enter into the question of how to set to work, either by giving the legal notices, placing the works in defined positions, or by avoiding erecting the line in such a way that it may have to be removed at the bidding of any small tenant on the way. A great deal may be learned by perusing the Act, and it is therefore advisable that any one who contemplates studying for the line, should make it his first duty to purchase the Act, which can be obtained from any law stationer, price 1s. 1d., post paid, and carefully note it from beginning to end. When this is done, great pains must be taken to conciliate the road surveyors, trustees, landowners, and others on the route laid out for the proposed line. If you purpose to go underground the difficulty is not so great, but we at present have to deal with an overground line upon poles. We have found it of great assistance to be prepared with a small model of the line, and with instruments and batteries, such as are to be used, and that a lecture given in local schoolrooms, or in the Town-hall, if the place can boast of one, is a sure means of making friends, and of clearing the way before you. Only induce the landed magnates to take the chair, and they will be sure to contribute their aid and patronage sufficiently to enable you to progress with your work so far. Little places as well as large ones require care, but the parson of the village church who presides is no less help than the landed squire, for he has it in his power to still many a troubled wave; and if he is a decent fellow—and most parsons are decent fellows—he will give you a lending hand, and a strong one too. In this way the writer of these lines passed through a length of 174 miles, and erected his line of telegraph not only unresisted, but with facilities given to him with a degree of good nature perfectly astounding, when it is considered without prejudice how much a line of telegraph disfigures a pretty country.

If once the way is clear, the survey may proceed, and, with due care, this should be made so complete as to save much difficulty and trouble in the construction and future maintenance of the line. On a railway, small stakes should be driven in, to mark the spot where each pole is to be placed. These can be purchased, for 7s. 6d. per 100, of any lucifer match dealer; they may be made of common deal, 1½ inch square, by 18 inches in length, and it will often be found useful to have some rounded for special "marks," as, for instance, testing posts where shackles are to be inserted, or where branch lines diverge, and to check the number of poles, at stated intervals, by the survey book. They serve to keep a distance check, too, on all the stores, time, labour, and expenditure, when the construction begins. On highways, these stakes cannot so well be used; they are more subject to be removed, or to be in the way of the traffic. In this case a mark on a wall, like a broad arrow, or a small streak of lime, or paint, will answer the purpose, but if the stakes can be used in hedges, so much the better.

The appearance of the line will be greatly benefited by keeping the poles as much as possible in a straight line, and with the tops level one with the other. Nothing looks so bad as to see the wires rising and falling at every cross-road or gate-post, and, after all, it only saves a few feet of timber in each case, so it is not worth while to spoil the look of the work, by an endeavour to save a few pounds in the prime cost. The poles should be, in every case, 28 feet in height, or, better still, 30 feet, for this will give room for six wires, resting on three arms, leaving eight inches of pole above the top arm. If the pole is set in the ground five feet four inches, and the arms are ten inches apart, there will be a space of 22 feet four inches between the road and the bottom arm, and, including the height of the insulator, 23 feet between the roadway and the lowest wire, and this is ample to permit a load of hay, or one of Wombwell's wild beast shows to pass under. These are the only impediments that have come to the writer's knowledge, so far as height of line is concerned. Place your poles, on an average, 70 yards apart, if on a railway, and not more than 60 yards apart, if upon the high road. On a railway, as you prefer going over all tunnels and bridges, make your ground on the top of cutting embankments, and, when you come to level ground, or earthworks, keep as far from the metals as possible, always bearing in view that uniformity already alluded to.

(To be continued.)

THE INTERNATIONAL EXHIBITION, 1862.

The Report of the Jurors appointed to adjudicate on the various contributions to Class XIII., consisting of telegraphic materials, electrical and philosophical instruments, recently published, is one of considerable importance to those engaged in their preparation and manufacture; and its reproduction in our columns will doubtless be acceptable to our readers generally, and probably we shall have occasion frequently to refer to the facts and opinions contained and expressed therein.

The onerous duty of compiling the Report was entrusted to and ably performed by Mr. Fleeming Jenkin, C.E., the Associate Juror and Reporter. The following is a list of the Jurors:—Sir David Brewster, K.H., F.R.S., Edinburgh, Principal of Edinburgh University; Charles Brooke, F.R.S., London, Surgeon to Westminster Hospital, 16, Fitzroy-square; Dr. Dove, Chairman, Zollverein, Professor of Natural Philosophy, and Principal of the Academy of Sciences, Berlin; J. P. Gassiott, F.R.S., London; James Glashier, F.R.S., London, Superintendent of the Meteorological and Magnetic Department, Greenwich Observatory, Greenwich; Colonel Sir H. James, R.E., F.R.S., Superintendent of Ordnance Survey, Southampton; G. Carston, Denmark, Professor, Kiel; Edward Kraffs, Austria, Member of the Council of Civil Engineers, Vienna; Mathieu, France, Member of the Institute and of Bureau of Longitude, Examiner of the Polytechnic; Carlo Mettencci, Italy, Senator; Major-General Sabine, R.A., F.R.S, London, President of the

Royal Society; W. Thompson, LL.D., F.R.S., Professor of Natural Philosophy, University of Glasgow; C. Wheatstone, F.R.S., London, Professor of Experimental Philosophy, King's College.

REPORT ON ELECTRICAL INSTRUMENTS.

By FLEEMING JENKIN.

THE following Report is divided into five main heads or chapters. The first is introductory, and contains only general reflections suggested by the instruments exhibited. In the four remaining chapters the instruments are described in detail; a classification under four main heads, according to subject matter, has been adopted chiefly to facilitate reference to any particular instrument or class of instruments. With the same view, each main head or chapter has been subdivided into sections, each containing some special group of instruments. The sections, or subdivision of the introductory chapter, may be considered as so many separate introductions corresponding to the separate chapters.

It is hoped that this arrangement, according to subject matter, will be found convenient. Its defects are that it separates the instruments shown by each exhibitor, and that the order in which the instruments are described in no way corresponds to the order in which they appear in the catalogues, nor to the country from which they are sent; but, on the other hand, it has the great advantage of bringing all similar instruments together, facilitating description, comparison, and future reference. It also allows the various groups to be coherently placed.

1. *General Remarks.*

THE electrical instruments now exhibited are numerous and excellent, whereas in 1851, the Jury Report states that they were but few in number. On that occasion, moreover, telegraphic apparatus were contributed by only two foreign exhibitors, while a fair proportion of those now shown have been sent from abroad.

The past eleven years have not been marked by any great discovery in electrical science, nor by any very important novelty in the practical applications of its principles. We have to register no such marvellous invention as the electric telegraph, nor any new motive power superseding steam. On the contrary, it must be acknowledged that many sanguine anticipations in this direction remain unfulfilled.

We have, on the other hand, to record a great extension of the telegraphic system, and especially the introduction of submarine cables. We have also to describe considerable improvements in all telegraphic apparatus, and various excellent applications of electricity to philosophical and practical purposes. There is cause for satisfaction in the fact that scarcely any bad and few indifferent instruments are exhibited. The workmanship is generally excellent, and in almost every case the design is based on a clear perception of the nature of the duties which can be advantageously performed by electrical means. Thus, whenever the electrical current is unavoidably employed to do work, as in releasing the escapement of clockwork, or in propelling the index of dial instruments, it will be found that in the instruments now shown, the work is reduced to a minimum by admirable workmanship, and by the lightness of those parts which are alternately at rest and in motion.* On the other hand, wherever mechanical effect, or, as some would call it, actual energy, is employed to develop electrical effects, as little work as possible is wasted. With this view, care has been taken to diminish the weight and friction of the moving parts; rapid or frequent alternations of rest and motion have been, where possible, avoided; and the relative resistances of the various parts of the circuits used have in many cases been carefully adjusted. The absence of useless though specious inventions is illustrated by the fact that electromotors, or machines for the production of motive power by the voltaic current, are few in number, and quite unimportant.

The researches of Dr. Joule have shown that with the present prices of materials, it would be utterly vain to expect that the power to be obtained from the conversion of zinc into its sulphate, should compete economically with that resulting from the combustion of coal. Let a battery be invented in which a cheap material only is consumed, and it will then be time to consider which is the best arrangement for converting the voltaic current into mechanical effect. At present, on the contrary, both in the magneto-electric signalling instruments, and the magneto-electric light, we see the usual sources of power successfully used to produce various dynamic electrical phenomena. In facts like these we note the influence of that great and recent discovery, the definite and mensurable correlation or the equivalence of the various physical or natural forces. This discovery, which in future times will stand out clearly as the scientific triumph of the century, enables us to measure accurately the shortcomings of our combinations for the transformation of energy, by comparing the effect actually produced with the possible maximum; it thus both sets a limit to our expectations, and shows how nearly we have approached that limit. It has already swept away whole crops of foolish, baseless contrivances, and barred many paths of useless research; but although its indirect influence on the instruments we are considering is clear, we cannot point out any special invention or contrivance, which is its direct and immediate consequence. It is moreover to be regretted that no apparatus is exhibited for the exemplification and popular demonstration of those laws of correlation which are already firmly established.

* This excellence is perhaps carried to the highest pitch in Professor Wheatstone's dial instruments.

2. *Construction of Telegraphic Lines.*

The successful establishment of *submarine telegraphic communication* constitutes the most remarkable achievement brought into notice by the apparatus exhibited. In 1851, the possibility of such communication had been barely established by a correspondence maintained for some hours between Dover and Calais. Now, after many failures, nearly nine thousand miles of insulated and submerged wire are successfully at work, and a single manufacturer exhibits specimens of twenty-eight successful cables, varying from 2 to 1,500 miles in length. One specimen shows the bare insulated wire by which our armies in the Crimea were kept for some months in hourly communication with this country. A second shows the cable by which the Atlantic itself was traversed;—a great success marred by failure after a few weeks' work.

Gutta-percha, the insulating substance proposed, and to some extent used in 1851, is still found the best; and it is satisfactory to know, after eleven years' experience, that not one yard of submerged wire insulated with this material has been known to decay. The well-known failures of the Red Sea, the Atlantic, and some other cables, cannot be traced, as is sometimes supposed, to any inherent defect in gutta-percha.

Some failures have undoubtedly been due to flaws resulting from imperfect manufacture or manipulation, and some to mechanical injuries received afterwards; others have been caused by the absence of sufficient electrical tests for the timely detection of these flaws and injuries: but the greatest number of failures may be attributed to the corrosion of the outer protection of iron wires, which has invariably been accompanied by the breaking up of the cables into short separate sections, defying repairs.

One by one, these causes of failure have been discovered and eliminated, with such success, that the cables lately laid have thus far been uniformly successful. The electrical tests have especially been brought to great perfection, and indeed these researches into the electrical properties of the materials used as conductors, or insulators, and into the phenomena accompanying the transmission of signals, have been prosecuted with such diligence and success, that they may also be said to form a new branch of electrical science. The whole subject has been rescued from empiricism, and made the matter of accurate measurement and calculation. Daily, fresh discoveries are made, and fresh methods of investigation employed, and some of the most interesting instruments exhibited are connected with this branch of electricity.

India-rubber is the only material yet known which can be used as a substitute for gutta-percha in the insulation of submarine or underground wires. In 1851, India-rubber was condemned as unfit for this purpose, but since then its preparation has been so much improved, that it is now in some respects even superior to gutta-percha; but further evidence of its durability is required. A short cable, insulated by india-rubber, is about to be laid in the Persian Gulf; and india-rubber covered wire has been used for various purposes on land with considerable success.

It is worthy of remark, that the Dover-Calais cable, of which a specimen was exhibited by Mr. Brett in 1851, and which was laid in the autumn of that year, remains at work, and is still the type of all successful cables.

Land lines are now constructed much in the same manner as in 1851, with some improvements in detail. Their extension has been

enormous. Europe is now covered with a network extending to Constantinople, and past St. Petersburg and Moscow, deep into Russia, approaching China. In Europe it is calculated that there are now about 100,000 miles of line in use; and about 50,000 miles in the North American States. India in 1860 possessed 11,000 miles of wire, with 136 offices; in Australia there are between 4,000 and 5,000 miles in use.

In Great Britain the Electric and International, and British and Irish Magnetic Companies alone now own nearly 11,000 miles of line, and 50,000 miles of wire. In 1851, little more than 10,000 miles of wire had been erected. Private lines have also been established in several of our large towns. Their success has been chiefly forwarded by the admirable inventions of Professor Wheatstone.

Underground wires have been almost wholly abandoned, as in this position both gutta-percha and india-rubber have been found to decay rapidly.

(To be continued.)

TELEGRAPHIC MEMORANDA.

(Continued from p. 5.)

Telegraph companies victimised by professional "*smashers*." An individual—generally a woman—presented an "urgent" message, together with a counterfeit half-crown, receiving the change in current coin. The message, when delivered, was found in every instance to have been an impudent hoax, but was occasionally productive of considerable embarrassment to the unfortunate receiver. Stations in the charge of female clerks were invariably chosen for this system of depredation.

An International Telegraph Congress held at the French Foreign Office, under the presidency of M. Drouyn de Lhuys, and composed of the representatives of the different Powers. The object being no less than to unite the Old to the New World, according to a plan proposed by M. Balestrini, a member of the College of Civil Engineers, Paris.

The communication through the Malta and Alexandria cable interrupted for a brief period.

A prospectus issued by the United Kingdom Telegraph Company explanatory of the principles upon which its operations were conducted. Along the great line of the company, between London, Birmingham, Manchester, and Liverpool, messages of twenty words were transmitted at the uniform charge of 1s. A second trunk line was rapidly approaching completion, embracing the important towns of Northampton, Leicester, Nottingham, Sheffield, Barnsley, Wakefield, Leeds, Hull, Bradford, Halifax, Rochester, and Huddersfield. The company had secured upwards of 600 firms and individuals in the large telegraphing towns as subscribers, to bring the company's wires to their respective towns. The result of the company's determination to extend its lines to large towns only, as capital might be subscribed by parties interested, which constituted the company, in fact, a consumer's company. The success which attended the adoption of such a plan may be inferred from the fact that at Hull alone £4,000 was subscribed by nearly 60 of the leading merchants, brokers, &c. It appears from the report that the gross number of messages sent in this country in 1850 reached 64,734; in 1859 they had increased to 1,575,487, or 2,400 per cent. The revenue of the two old companies in 1859 amounted to £275,704, in 1860 to £297,781, in 1861 to £307,602, and in 1862 to £318,462, showing a continuously progressive increase, in spite of the depression of trade and of the much lower tariffs introduced.

In America, in 1859 upwards of 5,000,000 messages were sent, at an average charge of 1s. 4d. to 1s. 8d., producing (exclusive of press work) £400,000. In the United Kingdom the same year, 1,575,437 messages only were sent, the average charge being about 3s. 6d., and the gross receipts (inclusive of press work) £275,704.

A company formed, with a capital of £100,000, in 10,000 shares of £10 each, to establish telegraph communication at Cape Race, in connection with a light-ship.

A deputation from the Cape Race Light Signal and Telegraph Company, introduced by E. Baines, Esq., M.P., had an interview with the Right Hon. T. Milner Gibson, at the Board of Trade.

The *Levant Herald* announces that the negociation between the Porte and Her Majesty's Government, for a telegraphic service to India, had been concluded, and a convention on the subject signed.

Allotment of Shares made by the Atlantic Telegraph Company.

Information received from Calcutta that the first portion of the Persian Gulf Cable, manufactured by Messrs. Wells & Hall, and sheathed by Mr. W. Thomas Henley, had arrived safe at Gwader, on the Mekran coast of the former, and that the telegraph employés had succeeded in erecting some 280 miles of land line from Kurrachee, considered the most inhospitable and repulsive coast in Asia.

A series of three lectures delivered, at the Royal Institution, on the "Electric Telegraph," by Professor Thomson, F.R.S.

A paper on inventions relating to Submarine Telegraph Cables read, by J. Mackintosh, Esq., at the Inventors' Institute; the paper had also special reference to the testing of various compounds used for insulation, and also the testing of their impermeability.

A telegraphic message, which left San Francisco on the 2nd of June, at 9.20 p.m., brought by the "China," which sailed from New York on the morning of the 3rd, and which arrived at Queenstown on the night of the 12th, was transmitted to St. Petersburg on the 13th. The whole time occupied in transmitting the message, from San Francisco, on the Pacific, to St. Petersburg, on the Neva, being ten days and a-half, nine and a-half of which were consumed in traversing the Atlantic by the steamer.

The chairman and directors of the Channel Islands Telegraph Company have an interview at the Treasury with the Right Hon. Frederick Peel, in reference to the restoration of the line.

The Telegraph Clerks' Fund established, under the patronage of the Right Hon. the Lord Mayor, and the directors of several telegraph companies.

A paper read before the Royal Society, by Mr. C. F. Varley, on "the Relative Speed of the Electric Wire through Submarine Cables of different lengths, and a Unit of Speed for comparing Electric Cables by bisecting the Electric Wire."

An interruption occurs in the operations of the Malta and Alexandrian Cable, the fault believed to be near the shore end.

Bonelli's Telegraph Bill read a third time and passed.

A meeting of gentlemen interested in the progress of submarine telegraphy held at the offices of James M'Connell, Esq., C.E., 2, Dean's-yard, Westminster, to consider the system of Submarine Telegraphy proposed by Capt. Selwyn, R.N.; the following resolution was unanimously carried:—"That, in the opinion of this meeting, Captain Selwyn's invention is deserving of trial." And on the motion of Mr. Henry Danby Seymour, M.P., seconded by Lord Richard Grosvenor, it was unanimously carried:—"That a committee be appointed to consider the best means of carrying out the above resolution, and to open a subscription list, and that such a committee consist of the following gentlemen, with power to add to their number:—His Grace the Duke of Sutherland; the Right Hon the Earl of Shrewsbury and Talbot; Lord Richard Grosvenor, M.P., F.R.G.S.; Admiral Sir E. Belcher, C.B.; Mr. H. Danby Seymour, M.P.; Thomas Allan, Esq., C.E.; Cornelius Varley, Esq.; and James McConnell, Esq., C.E."

The Return of the Total Expense of laying the Telegraph Cable between Malta and Alexandria, published by order of the House Commons, specifying, separately, the cost of the cable, the expense of laying it, and all other items of expense; of the number of messages, and the gross receipts from all sources; and copy of the contract with Messrs. Glass, Elliott, & Co., or any other persons, for the working of the line.

The nature and extent of the injury to the Malta and Alexandria Cable explained before the House of Commons, in reply to a question from Mr. Crawford, M.P.

The directors of the Atlantic Telegraph Company advertise for tenders for the manufacture and laying of their cable.

The Mediterranean Extension Telegraph Company (Limited) announce that the improvement in their revenue had been such as to render it unnecessary for the company to apply to Her Majesty's Government for assistance, under the guarantee, and that the company's cables were in excellent working order. The usual dividend was recommended to be paid, and a sum of £544 18s. 2d. to be added to the reserve fund.

The London District Telegraph Company, although not in a position to "deal with profits," the directors expressed their confidence in the undertaking, and, comparing the present state of things with the past, they had reasons to anticipate a more cheering future. In 1860 their loss was stated at £2,168; in June, 1861, £2,177; in December, 1861, £1,995; in June, 1862, £1,077; in December, 1862, £894; and on that occasion to June, 1863, only £440.

The directors of the Electric and International Telegraph Company were enabled to report to the proprietors that the condition of the undertaking was satisfactory; 784 miles of line and 2,666 miles of wire had been added to the company's system, and that the revenue of the company from all sources amounted to £117,210 4s. 8d., exceeding that of the preceding six months by £14,843 4s. 8d. The surplus of profit on the six months amount to £39,061 17s. 5d., and a dividend of £3 10s. per cent. for the half-year was recommended. The amount of mileage as follows:—

Miles of line	8,006
Miles of wire	36,921
Number of instruments	4,163

The United Kingdom Telegraph Company held their third annual meeting of shareholders at their office in Gresham House. The report states:—"The directors having gone carefully into the accounts are of opinion that, on the operations of the last year, a balance was earned of £2,699 19s. 5d.; but seeing the incompleteness of the company's system, and the work still to be accomplished, it was thought more prudent to place that sum to the credit of construction than to declare so small a dividend as this amount would have enabled the company to pay." The report showed that the anticipations of the company as to the increase in the number of shareholders, in consequence of the company's determination to extend their wires to all those towns affording guaranteed support, had been fully realized: thus, in Glasgow there were 133 subscribers; in Newcastle-on-Tyne, 42; Edinburgh and Leith, 69; in Hull, 53; and so on of other places; whilst the total number amounted to 734.

A deputation from the Atlantic Telegraph Company waited upon the Duke of Somerset to request that the Board of Admiralty would grant the use of a vessel for making a more complete survey and soundings of the bed of the ocean near the coasts of Ireland and Newfoundland, and would also give the use of the Government ships for the conveyance and laying of the cable across the Atlantic.

A table, supplied to manufacturers, &c., by the Atlantic Telegraph Company, showing the "operation of the electrical laws affecting the speed of working through long submarine cables, exemplified in the weight of insulation in proportion to copper, required to attain given rates of transmission per minute," ascertained by Cromwell F. Varley, Esq., and Professor Thomson, F.R.S.

Information received that the injury in the Malta and Alexandria cable had been repaired, and that the cable was again open to the public.

The Marian Moore transport vessel leaves the Thames with 170 miles of the Persian Gulf cable on board.

A violent storm passes over the metropolis, causing considerable inconvenience and loss to the various telegraph companies.

Experiments made with the Bonelli Company's telegraphic apparatus between Liverpool and Manchester, which were reported as eminently successful. Every message being transmitted with remarkable accuracy at the rate of over 400 words per minute.

The Atlantic Telegraph Company announce that the capital necessary for the carrying out of this important project in the best manner had been provided, and that tenders and specimens from eight contractors had been received, in reply to the company's advertisement. These were all submitted to the scientific committee appointed by the directors, and consisting of Captain Galton, R.E., Professor Wheatstone, Professor Thomson, Mr. W. Fairbarn, and Mr. Joseph Whitworth. This committee sent in their report, unanimously recommending the board to accept the tender of Messrs. Glass, Elliott, & Co. The company had, therefore, accepted Messrs. Glass's tender, and entered into a contract with the firm, whereby the latter were bound to manufacture a cable of the best description to be approved of by the scientific committee and the Board. They also undertook to lay the cable across the Atlantic in 1864.

The Telegraph to India Company report that they had received the first half-yearly payment of £1,260 from Messrs. Glass, Elliott, & Co., under the arrangement for working the Alexandria and Suez line. And the directors recommended that a dividend of 5 per cent. per annum be paid to the shareholders, free of income-tax, for the half-year ending June 30, 1863, leaving a balance of £115. It was also stated that the company had received the concession of the El Arish line, and that a new company had been registered under the title of the Syrian Telegraph Company to carry out the same, should it be deemed advisable to do so.

Bonelli's Telegraph Company open their wires for public business (18th September) between Liverpool and Manchester.

The British and Magnetic Telegraph Company successfully lay a submarine cable across the Bristol Channel at New Passage, Messrs. Glass, Elliott, & Co. being the manufacturers and the engineers, under whose superintendence the cable was laid.

Successful experiments made with Bonelli's Typo-Telegraph, between Paris and Boulogne, a distance of nearly 170 miles.

The last freight ships, with a portion of the Persian Gulf cable on board, leaves the Thames for Bombay.

Information received that Colonel Stewart, Sir Charles Bright, Captain Stewart, Mr. J. C. Laws, and Mr. F. C. Webb had arrived at Malta, in the steam-ship, "Valetta," from Marseilles, and had passed on in the same vessel to Alexandria, for the purpose of superintending the laying of the electric cable in the Persian Gulf. The ships forming the squadron for conveying the cable to its destination will rendezvous at Bombay, whence they will proceed to lay their respective sections. The submergence of the cable is to commence as soon as possible. The staff of electricians, telegraphists, &c., have been sent in the various cable-ships, all of which have left England, and the early ones must now be at or near Bombay. The submarine line will be laid in four sections, between Bussorah, at the head of the Persian Gulf, and Kurrachee, having intermediate stations at Bushire, Khasah, and Gwader. The land line from Bussorah to Bagdad, and thence through Asia Minor, is being proceeded with with all possible dispatch. The line is expected to be in full operation about the month of July, 1864.

Two additional cables ordered by the Ordnance Select Committee of the War Department. One, which is some miles in length, is exactly similar to the first cable supplied for that purpose some two years since, and consists of a No. 16 copper, insulated with three or four coatings of india-rubber, and the only protection it has is a serving of hemp, which is afterwards tarred. Notwithstanding the apparently fragile construction of these cables, it is satisfactory to know that they are most durable. The one first brought into use in the gunnery experiments by Captain Noble and staff is, if anything, in more superior condition now than it was when first purchased; its insulation remains perfect. We dwell upon this point with much pleasure, because it will have a greater tendency to establish confidence in the effectiveness of cables, as now manufactured, than whole volumes of barren assertions, and heaps of controversy, and it is of far more value than experiments made upon a small scale by the partizans of this or that method. We may just observe, by the way, that india-rubber insulation has made great progress during the year; a greater number of miles having been manufactured than the whole that had hitherto been made since insulation first became a necessity of telegraphic extension. The other cable is of more complicated structure, consisting of four separately insulated stream conductors, thrown up with longitudinal lines of marlin, and the whole very neatly braided over with hemp, by a new process, and afterwards tarred. The extremities of this cable are divided into two parts, each consisting of two separate conductors, braided over and strengthened in precisely the same way as the main body of the cable; this bisection of the ends is required for convenience in attaching to the electro-ballistic apparatus, and the targets, &c.

A cable is thus produced of immense strength, and yet so light as to be handled, payed out, and moved about with comparative ease and facility.

It will, doubtless, be of great service in the new marine experiments about to be instituted in Shoeburyness. It is intended, of course, to be partly under water while in use—indeed the whole of it, excepting the bisected extremities; and it would be difficult to conceive of a cable more suitable for the purpose, and will tend not a little to impress the beholder that this is a method of construction eminently adapted for deep sea purposes, as combining the three great requisites, *strength*, *lightness*, and *durability*. The insulation is of india-rubber, and the manufacturers, Messrs. Wells & Hall, who have supplied the whole of the cables for the Shoeburyness and other experiments of the Ordnance Select Committee.

The application of electricity by means of telegraph cables, and the beautiful instrument of Major Narves, in recording the results of the important experiments now in progress at Shoeburyness, is worthy of being recorded in this general review of the telegraphic events of 1863. The science of warfare, both for attack and defence, would seem to be entering on a new phase, and, seeing that, with the exception of our own favoured land, the whole world is—one part deluged with blood, and the other maintaining vast armies on a war footing, and slumbering, as it were,

in a volcano, it is surely some satisfaction to know that, while we sincerely hope for the best and are fain to exercise the demon of war, we are yet determined to keep pace with the advance of science, and secure its assistance, to keep us fully prepared for the worst.

On the whole, therefore, we may congratulate our readers on the advance that has been made during the past year. Nothing very striking has occurred, it is true; nevertheless, our progress, although slow, has been sure, and moreover, has been of that satisfactory character which affords abundant ground for congratulation and renewed exertion.

THE ORAN AND CARTHAGENA SUBMARINE CABLE.

The French telegraph screw steamer, *Le Dix Decembre*, which had been lying for some time opposite the factory of Messrs. Siemens, Halske, & Co., the well known telegraph contractors, left the Thames on the 16th ult. for its destination, having on board 130 knots of submarine cable, destined to connect the Spanish town, Carthagena, with Oran in the north west of France. Considerable amount of interest is felt amongst telegraphic engineers and others with respect to this renewed effort to lay a deep sea cable, and more especially as the cable is of an entirely novel construction, and the means adopted for paying out the cable are dissimilar to those hitherto adopted. The cable is wound upon a cylinder built within the vessel, and which will be caused to revolve, in the paying out of the cable, by steam power, which also regulates the speed of the vessel. The greatest depth at which the cable will be laid is 2,600 fathoms.

The outer covering consists of a double layer of hemp strings of the strongest material, saturated in Stockholm tar, laid on spirally, and under considerable tension, the twists of the two layers running in opposite directions.

It is then finally covered by a flexible copper or brass sheathing, composed of bands of sheet copper or brass, put on spirally under the influence of great pressure, and with each succeeding turn overlapping the preceding. The covering thus produced resembles the scales of a fish, affording perfect protection without wanting in pliability.

The phosphuretted copper or brass applied for the purpose will not corrode in sea water, but remain in perfect condition for a great number of years.

The tensile strength and low specific gravity of the cable, and the impossibility of the metal sheathing uncoiling, or kinking, will remove all difficulties and risks connected with the laying of iron-covered cables of the description hitherto exclusively adopted, and also will be the means of enabling the cable to be lifted in very great depths, and after the expiration of many years.

The lightness of these cables make them well adapted for many over-ground purposes where electric wires are required—easy to be handled and transported, and of considerable strength—as for military lines, electric target wires, leading wires for mines, &c. They may with safety be laid on common ground, as even the crossing of carriages will not injure their insulation. They may be made in sizes not exceeding three-sixteenths of an inch in diameter, and at moderate prices, not exceeding those of similar iron-covered cables.

LAW INTELLIGENCE.

Scottish Vulcanite Company, Limited, *v.* Benda.—The plaintiffs in this action were assignees of a patent, dated 4th March, 1851, No. 13,542, granted to Alfred Vincent Newton, for "Improvements in the preparation of materials for the production of a composition, or compositions, applicable to the manufacture of buttons, knife and razor handles, inkstands, door knobs, and other articles where hardness, strength, and durability are required." This patent was really taken out for Charles Goodyear, the American discoverer of vulcanizing rubber, and the subject was the substance called, in America, "hard gum," and in England, "hard rubber," "vulcanite," or "ebonite," which is produced by continuing the process of vulcanizing, to its utmost extent. This "hard rubber" can be made by both the processes used for making soft vulcanized rubber, *i.e.*, by either placing the pieces of pure rubber in a bath of melted sulphur, and leaving them there until the vulcanization has taken place, or by blending the sulphur and rubber in a masticator, or by rolling, and vulcanizing the compound by steam, hot water, or hot air. The plaintiff's patent was for the latter process only, and the preparations of rubber and sulphur directed to be used, were not less than four ounces, nor more than one pound of sulphur to one pound of rubber. As their specification originally stood, the introduction of French chalk, resins, gum shellac, and other pigments into the compound was directed, but this part of the specification was abandoned, by a disclaimer allowed at the commencement of this year, by which, also, the preparation of rubber and sulphur were considerably altered. The patent also included the manufacture of hard gutta-percha by the same process. The plaintiffs had, for some time, threatened many of the English and Scotch manufacturers of hard rubber. This action, however, was the only one ever commended by them, and was brought, not against a manufacturer, but against Messrs. Benda Brothers, of Newgate-street, commission agents, for selling combs of hard rubber, consigned to them from Hamburg. Numerous objections to the plaintiffs' patent, involving questions of law, as well as of fact, were raised by the pleadings. The principal and the only one which it was eventually necessary to decide being, that both hard rubber and hard gutta-percha were, at the date of the plaintiffs' patent, well known; the former having been discovered by Mr. Thomas Hancock (of the firm of Messrs. Charles Macintosh & Co., Manchester), at the same time as he discovered the process of making soft vulcanized rubber, and included in his patent of that process, dated 21st November, 1843, No. 9,952, and the latter by Mr. Charles Hancock, and included in his patent of 12th January, 1846, No. 11,032. Another patent, taken out by Mr. T. Hancock on the 18th March, 1846, No. 11,135, was relied upon as directing the application of hard rubber for many of the purposes mentioned in the title of the plaintiffs' specification. The issues of fact in the cause came on for trial at Guildhall, before Chief-Justice Erle, and a special jury, on Tuesday, the 8th December, and the two following days, Mr. Bovill, Q.C., Mr. Hindemarsh, Q.C., Mr. Aston, and Mr. Ledgard, appeared for the plaintiffs; Mr. Grove, Q.C., Mr. Webster, and Mr. Garth, for the defendants. In support of their case the plaintiffs tried to prove, by the evidence of Dr. Miller, and other scientific witnesses, that the preparation of rubber and sulphur, mentioned by T. Hancock, and of gutta percha and sulphur, mentioned by Charles Hancock, would not make hard rubber and hard gutta-percha, the proportion of sulphur being too little; also that the sulphur bath process was a total failure, and had been long since disused. They also called several witnesses to prove that hard rubber was not known until the plaintiffs' patent, and Dr. Lankester to prove that he was a juror at the Exhibition of 1851 of the Indiarubber manufacture, and recollected no specimen of hard rubber there except at Charles Goodyear's stall. The defendants were not able to call Messrs. Thomas or Charles Hancock, their health preventing their appearance in court; but to prove that Charles Hancock's mode of making hard gutta-percha was good, they called his son, Mr. Walter Hancock, who had made all the experiments necessary to enable his father to prepare his specification, and subsequently made many articles of hard gutta-percha, some of which he produced in court. To prove that hard rubber could be and was made under Thomas Hancock's 1843 patent, they called Mr. Woodcock, the manager of Charles Macintosh & Co.'s manufactory for the last thirty years. He proved that articles of hard rubber had been made by them, and exhibited in the show-rooms of their Manchester and London warehouses prior to 1850, and that a large number were in the Exhibition of 1851, some of which he produced. He also proved that the sulphur bath was used for making hard rubber, and was for many articles the best mode, and that hard rubber could be made with a much less proportion of sulphur than that prescribed by the plaintiffs' specification. Mr. Hindmarsh was stopped in his cross-examination of this witness by Chief Justice Erle, who suggested that unless the plaintiffs had some evidence to contradict these two witnesses, it was useless going on. The jury here stated that they were all agreed that the defendants had made out their case. After a consultation among the plaintiffs' counsel, Mr. Bovill stated that they were not prepared with evidence to upset that given on behalf of the defendants, and that the plaintiff elected to be nonsuited. Mr. Grove then asked the judge for the certificate that the defendants had supported their notice of objection, which was granted, the Chief Justice remarking that the nonsuit was really a verdict for the defendants.

Rooper *v.* the Electric and International Telegraph Company.—Telegraphic Messages and the Public.—This was an action to recover 24s., money alleged to be charged in excess as porterage or despatch money upon a telegraphic message.—Mr. Haynes appeared for the plaintiff, and Mr. Cohen was counsel for the company.—Mr. Haynes said that this was a most important public question, and one that required consideration, although the amount appeared small. The plaintiff is a solicitor in Lincoln's-inn-fields, and some time ago he was stopping at Pwllheli, in Wales. A telegraphic message was forwarded to that place from London, 4s. being paid for the message, and 6s. porterage. The nearest station to Pwllheli is Carnarvon, and a horse messenger took the message, but on his road he heard that the plaintiff had gone to Llanberis. The messenger followed, and ultimately delivered the message to Mr. Rooper at Llanberis. He was charged 24s. more porterage, and paid it, and this sum he now sought to get back.—His Honour: So far as you have gone there is no case.—Mr. Haynes: I rest my case on two grounds; the first is, that the contract was to deliver the message at Pwllheli, and the second that it should have been sent by a public conveyance, which would have conveyed it much more cheaply.—Mr. Cohen urged that the company was entitled to deliver the message to the person to whom it was addressed. This message was ad-

dressed to Mr. Rooper, and he had accepted it and paid the charge made. He could not now set up a claim for the money so parted with.—His Honour: I am quite of opinion that there is no case. The plaintiff might have refused to receive the message at Llanberis, but he adopted another course, and he could not now deviate from his own motion. He had paid the money and accepted the message, and must be bound by his own act.—Mr. Haynes: The contract is to deliver the message at Pwllheli, and surely your honour would not throw such immense power into the hands of the company as to say that they are entitled to follow plaintiff to Scotland.—His Honour: If there had been £10,000 involved, perhaps Mr. Rooper would have been greatly delighted to have obtained the message even then, but we are now dealing with this case.—Mr. Cohen: We are clearly entitled to follow the plaintiff, and he cannot now recover back the money. Our contract is to deliver the message to Mr. Rooper, and he has had it. Our charges are 1s. per mile, and that sum has been paid by plaintiff.—His Honour: I am of opinion that the plaintiff cannot recover. He might have refused to accept the message at Llanberis, but he did not do so, and, on the other hand, accepted it at the last place. The company make a stated charge, and the plaintiff paid it for the message.—Mr. Haynes then said, even if the judge were against him on this point, there was clearly an overcharge on the porterage.—Mr. Cohen objected, that the plaintiff had paid the porterage for the message, and he could not now set up an overcharge.—His Honour: The company are entitled to charge 1s. per mile, and if they have charged too much they must refund.—Plaintiff said that the landlady at the inn at Llanberis brought up the message, and plaintiff paid 14s. The landlady came up again, and said there was 10s. more to pay, and plaintiff paid it.—Mr. Cohen put in the receipt for 14s., and called attention to a printed notice on the receipt that the receiver of the message should not pay any more than the sum marked on the form.—His Honour said that plaintiff ought to have read the printed words on the form, and as there was a doubt as to the mileage, he would nonsuit the plaintiff.—Plaintiff nonsuited.

CORRESPONDENCE.

THE JURORS' REPORT ON CLASS XIII.

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—I shall be glad to know if you intend re-publishing in the pages of the *Telegraphic Journal* "The Jurors' Report of Class XIII. of the International Exhibition of 1862." I think it would be most advisable to do so. It may appear to some that a pamphlet some three or four months old, which has gone forth to the world unquestioned in any of its parts, is too stale and uninteresting an affair for resuscitation. To ordinary and superficial readers such a demurrer would certainly be unanswerable. But there are certain points concerning it which will suggest themselves to the thoughtful observer in a very different light, and which may be esteemed equally unanswerable on the opposite side. We must not forget that, in the Exhibition of 1851 telegraphy and electrical science through their instruments, manufactures, and mechanical adaptations were virtually unrepresented; and it is also notorious that in the Exhibition of 1862 this important department of mechanical science was all but ignored in comparison with other sciences of infinitely less moment. Mixed up as it was with a conglomeration of "Philosophical Instruments and Processes Depending on their Use," it suffered in every conceivable way. The mere sight-seer, after having left the building, had certainly no distinct idea which were philosophical and which electrical instruments that had passed under his rapid survey. Nor were more intelligent observers a vast deal wiser. But if it suffered in this way from want of that distinct prominence which was its due, it necessarily suffered tenfold more so in the appointment of jurors to report upon the class. The distinctive characteristic of Class XIII. had been all along philosophical. Except in the catalogues there was nothing to indicate that there was such a thing in the whole vast area of the building as specimens of telegraph wires, galvanometers, or any description of electrical and telegraphic apparatus. It followed, therefore, as a matter of course, that when the jurors were chosen, *three only and one expert* knew anything at all about the most important part of the contents of the class on which they had to adjudicate. The burst of disappointment and indignation which found vent when this became known is fresh in the memory of all. True, the few electrical jurors who were chosen were eminent in their profession, save that they have never failed to evince certain prejudices, and were biassed to an extent quite sufficient to incapacitate them for the impartial duties they had to perform. But even had this not been the case, the fact of their being, almost without an exception, either exhibitors in *propria personæ* or by proxy, utterly disqualified them for an appointment which they ought never to have accepted. In the matter of awards, therefore, everything turned out just as it was expected. Many were disappointed, and yet they were not disappointed when they came to reflect calmly on the whole affair. The truth is, the excellency of their productions were not appreciated, and how could it be otherwise?

The getting up of the report on electrical instruments, &c., devolved, as it would appear, mainly on the gentleman associated with the jurors of that class—Mr. Fleeming Jenkin. Hence it was a long time making its appearance—so much so, indeed, that many persons had began to forget the Exhibition which had given it birth. The report is none the less important on that account; and doubtless it will be considered that, on the whole, Mr. Jenkin has acquitted himself very creditably. The bulk of the readers of the *Telegraphic Journal*, however, have not, and will not have, an opportunity of judging for themselves on this matter, unless it is presented to them in your pages. I confess I should much like to see it there, and freely commented upon from week to week. By this means certain points would be brought under discussion which require to be thoroughly sifted. Mr. Jenkin no doubt is entitled to a great deal of credit, and his views and opinions, as therein recorded, are entitled to considerable deference; but there are many important points dwelt upon by him to which not a few will demur; it is highly desirable, therefore, that these should be thoroughly sifted. Besides, it must not be lost sight of that a juror's report of the International Exhibition is a weighty document, and is, therefore, treated as an authority superceding all others. It becomes doubly important, therefore, that all doubtful points should be cleared up; and where our author is at issue with facts, and experimental data are set at nought, it is the least we can do to protest against it; for opinions, even from a professor's chair, if they are at variance with known facts, should not go forth to the world without a corrective.

Brompton. JAMES SPICER.

[We had a portion of the report in print for our first number, but it was crowded out.—ED. T. J.]

TELEGRAPHY AND HER MAJESTY'S GOVERNMENT.

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—I cannot agree with your correspondent of last week—E. F. G.—in the matter of Government assistance to submarine telegraph projects. I, in common with most Englishmen, look with a jealous and suspicious eye on the dabblings of the Government in matters which may be safely left to the capital and enterprise of public companies to accomplish.

Hitherto, as becomes a constitution like ours—which we may proudly assert is the envy of the civilised world—the executive have carefully avoided meddling with projects which have the remotest appearance of entrenching upon what we may be allowed to term the peculiar prerogative of the British subject; and, whenever they have unwisely evinced a tendency to deviate from so desirable a course, the attempt has always been met with a burst of general dissatisfaction, which has invariably lapsed into an organised opposition before which the recalcitrant has invariably given way, and abandoned an assumed, untenable, and dangerous position. Without gliding imperceptibly into a political diatribe, I may be allowed to remark that, to this disposition of jealous watchfulness and prompt action we owe not a little of that constitutional freedom of which we are so justly proud.

Our Government has always abandoned with a good grace every essay of the sort on the slightest symptom of popular mistrust, and hence a great many people think they overstrain the matter, and err on the opposite side; if it be so, it is certainly an error on the safe side, at which no man should grumble. We have no cause to fear that our highly-favoured land will ever lapse into, or emulate, continental or even transatlantic despotism; still, we should be careful not to encourage any course of action that would give the slightest pretext for copying in any single thing the bad example of such blind guides. The lines of railways and telegraphs in the hands of the Government, and under their sole control, is an uncomfortable state of things for the Briton who, from necessity or choice, has taken up his abode in a land where such a state of things exists, and we may be sure he makes as little use as possible of the latter for very obvious reasons.

I deplore the depressed condition of submarine telegraph enterprise as much as your correspondent, but every ball will rebound in proportion to the force with which it has been hurled. The whole history of the world is but one long homily on the text that one extreme of necessity produces, or is succeeded by, its opposite—periods of intense excitement followed by flacidity and languor. Even personally, metaphorically, or otherwise, if a man kill the fatted calf this week, the chances are that he will have only the bones to pick next.

The presumptuous self-confidence manifested in our first essays on submarine telegraph projects, and the utter disregard of the commonest precautions, led to failure, and necessarily produced distrust among those who had been its most enthusiastic supporters. And, as over-sanguine people shiver under a wet sheet far more than moderately-tempered persons, the result is that the shivering fit is not over, and, therefore, another paroxysm of enthusiasm can hardly be expected until they become convalescent; but assuredly we do not require Government nerve and equanimity to supply the deficiency.

I deeply regret the Atlantic telegraph should languish for want of sustenance; it is no credit to the nation certainly that the funds are so long dribbling in for the proposed cable. But who are to blame? Your correspondent would throw the onus on the Government because they decline to give substantial assistance. This is not fair. The Atlantic Company have only themselves to blame; but doubtless, if they evince their worthiness of support, it will not be long in forthcoming from other quarters than Downing-street.

I rejoice in the prospect of our being put in daily communication with the teeming millions of the Orient; but I must say I would rather have had

the Persian Gulf telegraph the property of a company than of the Government. It seems somewhat strange that the India Board should be in advance of the times; usually the reverse is the case. Apparently the gigantic failures of submarine lines has laid private enterprise prostrate. This is a pity. Suppose railway projects had remained dormant in the same way, and Government had come to the rescue and constructed a few lines of its own, would that have been flattering to us as an enterprising people, of indomitable will and energy, not to be frightened at trifles? Submarine telegraphy languishes—granted. But it will come all right in time; wait for it, and do not seek to do that which you might live to regret.

H. I. J.

RE-EXAMINATION OF CANDIDATES BY INDIAN BOARD OF TELEGRAPHY.

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—Please state, through the medium of your paper, if it is imperative a candidate should not exceed the age of twenty-four, or if he is rendered ineligible if exceeding that age by a few months. Yours, &c.,

Glasgow, Jan. 6, 1864. D. K.

[Our correspondent had better write to the "Under-Secretary of State for India, India Office, London, S.W."—ED. T. J.]

TELEGRAPHIC NEWS.

THE vessel with the Otrant and Avelona cable on board, left the factory of Mr. W. T. Henley, at North Woolwich, on the 7th inst.

WE are glad to hear that Dr. Sutro, of 37A, Finsbury-square, has become honorary physician to the Provident Clerks' Fund, and that several new members have joined the fund during the last week.

BY the demise of Mr. John Watkins Brett a vacancy occurs in the direction of each of the following companies—viz., the Atlantic Telegraph Company, the Submarine Telegraph Company, and the Mediterranean Extension Telegraph Company.

THE Submarine Telegraph Company have given notice, that in consequence of the French Administration having determined to increase their rates to Spain and Portugal, the price of transmission of messages between England and those countries is necessarily increased.

BY an agreement entered into betwen M. le Vicomte de Vongy, Director General of Telegraphic Lines, and M. A. Callaud, of Nantes, and approved by the Minister of the Interior, the battery without a porous cell, invented by M. Callaud, is adopted for the telegraphy of the State. The system has been employed on the Orleans Railway Telegraph for the last five years.

A telegram received by the Electric and International Telegraph Company on the 6th inst., announces that the telegraphic station at Iakoutsk, on the route to China, was opened on the 2nd December; the distance from St. Petersburg being 5,700 verst. It is believed that messages which formerly took 23 days by post, will now reach that point in eight hours.

LETTERS have been received from Sir Charles Bright, Lieut.-Col. Stewart, Mr. J. C. Laws, and Mr F. C. Webb, announcing their safe arrival at Alexandria, and also of their departure to Aden, and from thence for Bombay, all well. The vessel *Assaye*, with a portion of the Persian Gulf cable on board, was spoken to near Cape of Good Hope, reported all well.

MR. L. W. COURTENAY, whose retirement from the secretaryship of the Submarine Telegraph Company we announced in our last number, has been succeeded in the important office by S. M. Clare, Esq., a gentleman who had been for some time employed under the company.

THE London District Telegraph Company are now constructing a private telegraph for the Speaker of the House of Commons, from his official residence, in Palace-yard, to the new stables, which have just been completed, in Millbank-street, Westminster.

THE authorities at the British Museum have requested Captain Shaw, of the London Fire Engine Establishment, to have a telegraph provided from the Museum to the Fire Brigade Station in Holborn. The London District Telegraph Company have just completed the communication.

THE Peruvian Government has determined to construct a network of telegraphy over the whole of its territory, consisting of 430,000 square miles, or four times the extent of that of Great Britain and Ireland. The population of Peru now exceeds 1,500,000. Several proposals have been received from eminent contractors to carry out the proposed system.

CAPTAIN SPRATT, R.N., retires into private life, after an honourable and useful career of thirty-two years, employed in the survey of the Levant and Mediterranean. His name will be honourably remembered in connexion with the assistance and counsel he was enabled to give, from his extensive hydrographical experience in those waters, in the several operations of submerging electric cables, some of which exist to this day as monuments of successful scientific undertakings.

THE Director-General of the Imperial Telegraphic Lines has been for some time engaged in negotiations with various Governments for reduction in the prices of telegraphic messages sent to foreign countries. He has succeeded in reducing the price of telegrams to Spain from 9fr. to 2fr. from the 1st of the present month. The telegrams to Switzerland, which at present pay 9fr., will be sent for 3fr. Thus commercial and private relations between France and foreign countries are becoming day by day less difficult.

THE Kingdom of Greece has 12 telegraph stations, all the messages between the Greek and European lines pass through Turkey, and consequently the rate is very high. There would then be a considerable interest in establishing a direct line between Greece and Southern Italy. It is known that there exists already a submarine cable from Otrante to Corfu, another is required from Corfu to Panras or Missolonghi, across the Ionian Islands. The depth of water would be small.

ON the 3rd inst., Captain Tyler, R.E., the Government Inspector of Railways, made his final inspection of the Charing Cross Railway. Among the gentlemen present were—Mr. Hawkshaw, the engineer; Mr. Wythes, the contractor; Mr. Eborall, the general manager; Mr. Knight, the traffic superintendent; Mr. Walker, the telegraphic superintendent of the South Eastern Railway; Mr. Cockburn, Mr. Saxby, and other officials. The examination commenced at the London-bridge extremity of the line, where Captain Tyler minutely inspected the working of the signals, both semaphore and telegraphic. At the junction of the main with the short line or arm, which is to connect the former with the future Cannon-street City terminus, the inspector entered the signal-box and rigidly examined the working of Mr. C. V. Walker, F.R.S.', admirable system of train signalling, which was considered satisfactory in every respect.

THE PORTLAND AND QUEBEC TELEGRAPH.—As may be seen from the following notice, taken from the Maine newspapers, a telegraph line is about to be constructed between Portland and Quebec:—The undersigned will petition the next Legislature as follows: "To the Honourable the Legislature of Maine.—The undersigned respectfully petition for an act to incorporate the Maine and Provincial Telegraph Company for constructing a line of telegraph from the city of Portland, by the most eligible route, to Quebec and other points in the British provinces, with the usual privileges of like corporations in this State.—J. J. Speed, Gorham, Me.; J. W. Lane, Portland, do.; S. C. Hay, Brooklyn, N.Y.; Theodore Adams, Philadelphia, Pa.; T. H. Wilson, Harrisburg, Pa.; Henry Morgan, Aurora, N.Y.; Nathan Randall, Homer, N.Y."

THE telegraph in Russia is making rapid progress. From a recent report published, it appears that on the 1st of January, 1862, there were no less than 19,530 versts of telegraph lines, and a total length of wire of no less than 32,330 versts. On these lines there were 169 stations, with 1,920 *employés* of all grades; 415 instruments, and 6,750 elements of Daniell's battery. During the course of the year the number of messages transmitted reached 627,000, of which 559,000 were paid for, or rated. The receipts of the telegraphic administration were 1,176,761 roubles: the receipts for inland messages being 1,048,020 roubles, and for foreign messages 128,742 roubles, besides 52,456 roubles which were received to the profit of the postal service, and 198,828 roubles for the foreign telegraphic lines. In comparing the preceding figures we obtain an excess of receipts of 156,146, representing about 4 per cent. per annum of the capital of 3,536,900 rubles, applied up to the 1st of January, 1862, to the organization of the telegraphic service.

IN the Turkish territories there are now twenty-eight telegraphic stations, of which twelve are open for night service (Adrianople, Chios, Elbassan, Gallipoli, Nissa, Routschouch, Salonica, Scutari, Smyrna, and Toultcha), nine during the whole of the day, and seven for a part thereof. One station, that of Ouzoundjowa, only works during the fair, which takes place yearly, from the 15th of September to the 8th of October. La Canée possessed a telegraphic station for some time. Since the interruption of communication between Candia and Chios the despatches are posted at Syra. Constantinople has two stations open for international correspondence—one at Stamboul, the other at Pera; the first is principally confined to the transmission of messages for the Ottoman Government, and the second for that of ambassadors and private persons. In the case of an interruption of the cable which crosses the Hellespont, the Dardanelles station is removed to Kalid-Bahas, and the despatches are subjected to an additional rate of 4fr. 50c. for their conveyance by boat from Kalid-Bahar to the Dardanelles. The tax upon messages between Paris and any Turkish station varies from 14fr. 50c. to 30fr., according to distance.

A TRANS-PACIFIC TELEGRAPH.—In the Message of the President of the United States to Congress the following passage appears:—"Satisfactory arrangements have been made with the Emperor of Russia, which it is believed will result in effecting a continuous line of telegraph through that Empire and the Pacific Coast." The President also recommends to the favourable consideration of Congress "The subject of an international telegraph across the Atlantic Ocean." Furthermore, the news by the *Etna* informs us that the report of the Hudson's Bay Company recommends the construction of a telegraph from Canada to British Columbia, and states that the requisite negotiations are in progress with the Home Government, as well as with the Governments of the two colonies." We have no means of knowing how far the preliminary proceedings have gone in any of these cases, and must forbear speculating until the papers bearing on the subject are published, which they must shortly be. The President announces definitely that arrangements "have been made with the Emperor of Russia" for a trans-Pacific telegraph, while he merely recommends the trans-Atlantic project to favourable consideration. It would appear from this that the former project is in a greater stage of forwardness than the latter; but it by no means follows that it will be completed sooner. Mr. Cyrus Field and his co-workers are making earnest efforts to secure the construction of the International Telegraph, and a large amount of stock has already been sub-

scribed. Glass, Elliott, & Co. offer most advantageous terms, and little besides the aid of the British and American Governments required to be secured to insure a start being made. The prospect of a trans-Pacific telegraph being commenced in earnest will probably give an impetus to this scheme, which will enable the yet remaining difficulties to be surmounted and induce immediate action. England cannot afford to allow the United States and Russia, by means of an overland line, to monopolise the advantages which would be drawn from the telegraphic union of the two continents. But whatever it may be, Canada is on the right side; if we cannot get communication with Europe *viâ* the Atlantic, we shall *viâ* the Pacific. The Hudson's Bay line will connect us with the latter, which must pass through British territory—a point Mr. Lincoln, in speaking solely of negotiations with Russia, appears to have overlooked. No telegraph, whether it comes from the continent to the eastward or the westward, can reach the United States unless Britain gives her consent. To an American citizen, Mr. Perry Collins, belongs the honour of having originated the proposition of a trans-Pacific telegraph. Years ago he travelled the immense distance from St. Petersburg to the mouth of the Amoor, and thence northward to the Behring's Straits, for the purpose of ascertaining whether the construction of a telegraphic line were possible. Mainly by his exertions the Russian Government was roused to the importance of the matter, and, that once done, they commenced the work and have prosecuted it with vigour. By the middle of next year it is anticipated that the wires will have reached their settlement at the mouth of the Amoor. They will thus be in possession of the longest telegraphic line in the whole world. To connect San Francisco with the Amoor, various routes are proposed. The coast line, it is agreed on all hands, must be followed northward from San Francisco, through Washington territory and the British possessions, into Russian America. It then remains to be considered whether the narrow Behring's Straits shall be crossed or whether a sea route further south shall be followed. The latter appears to be the favourite. If any of our readers will take a good chart they will see that in latitude 55 deg., longitude 160 deg. west, the Russian promontory of Aliaska, or Alyaska, extends in a south-westerly direction for many miles. Stretching all the way from the extremity of this promontory to Kamschatka, on the Asiatic side, are the Alutian Islands, which may readily be connected by means of short cables. The wires then might be taken round the coast of the sea of Okhotsk to the Amoor. The whole distance from Washington to London by this route would be upwards of 19,000 miles. Along more than 12,000 miles of this distance the telegraph will be stretched before the end of next year.

MISCELLANEA.

IT is estimated that 25,000 persons are engaged in Peru in obtaining india-rubber to supply the foreign demand.

IT is on record that the *Morning Chronicle* was the first daily English journal that availed itself of the application of the electric telegraph to report speeches and proceedings; the result of a railway meeting on a week evening in the Isle of Wight, being reported through the instrumentality of the telegraph on the South Western Railway, between Southampton and Nine Elms, a distance of 72 miles, and appearing in the paper the next morning.

WHEN Franklin made his discovery of lightning and electricity it was sneered at, and people asked, "Of what use is it?" To which his apt reply was, "What is the use of a child?—It may become a man!" When Galvoni discovered that a frog's leg twitched when placed in contact with different metals, it could scarcely have been imagined that so apparently insignificant a fact could have led to important results. Yet therein lay the germ of the electric telegraph, which binds the intelligence of continents together, and probably, before many years elapse, will "place a girdle round the globe."

IT is curious to stand in the instrument-room among 80 young ladies busily at work, and watch the different idiosyncrasies as developed in the manner in which each conducts her operations. One dashes at her instrument with an impetuous rapidity that soon brings to utter grief the "washers" which confine the noise of her "plungers" within some sort of bounds, and for whose replacement she is mulcted of some portion of her weekly pay. Another raps on slowly and steadily as part of the day's work to be done. Here a pair of bright black eyes, glistening from under a forehead from off which the hair has been pushed with a quick impatient gesture, are glittering impatiently as the little hand raps a sharp rebuke to a stupid correspondent in some distant part of the town or country. There a pair of sentimental blue eyes turns gladly from the completed message to the novel whose more exciting scene has been interrupted by an inquiry after the missing keys of some unromantic Smith or Brown. This girl is smiling or frowning over her work in evident appreciation of the message under manipulation; that plods steadily on her way, and would telegraph to the Tower the signature of her own death warrant, were such documents accustomed to pass that way, without the slightest idea that anything of particular importance had been passing through her hands.

EBONITE.—The venerable Thomas Hancock, in his *Personal Narrative of the Origin and Progress of the Caoutchouc or Indiarubber Manufacture in England*, states, "I remember at that time (1820), when exhibiting a piece of my solid rubber to an old gentleman, he examined it, and, returning it, made this remark, which bids fair to be realized, 'The child is yet unborn who will see the end of that.'"

TO CORRESPONDENTS.

Erratum.—Page 7, second column, third line, instead of "Bailey," read "Varley."

Lessons in Electricity and Telegraphic Manipulation will shortly appear.

Communications intended for publication must be authenticated by the names and addresses of the writers; not neccessarily for insertion.

Letters relating to Advertisements are to be addressed to the Publishers. All other letters and communications to be addressed to the Editor of the *Telegraphic Journal*, 5, Suffolk-lane, Cannon-street, London, E.C.

The *Telegraphic Journal* can be had of all news-agents in town or country, and at the various railway stations; or, it can be supplied, if preferred, direct from the Office on the following terms (paid in advance):—

	s.	d.
Quarterly	4	4
Half-yearly	8	8
Yearly	17	4

TO ADVERTISERS.

The *Telegraphic Journal* is the most effective medium for inventors, patentees, contractors, manufacturers of insulating materials and electrical apparatus to submit their various specialities to the consideration of secretaries and managers of telegraph or railway companies, and other persons engaged in electrical and telegraphic pursuits.

Clerks, assistants, manipulators, and instrument makers, seeking employment, &c., will find the *Telegraphic Journal* a ready means of making known their requirements.

Advertisements must be delivered to ensure insertion before SEVEN O'CLOCK on Thursday evening in each week. The charges for Advertisements are—

	£.	s.	d.
Whole page	4	4	0
Half ditto	2	10	0
Quarter ditto	1	7	6
Four lines and under (single column)	0	3	0

Single Advertisements from the country must be accompanied with stamps in payment.

SUBMARINE TELEGRAPHY AS AN ENTERPRISE.

IN our last number we endeavoured to show that Submarine Telegraphy is an enterprise which might be engaged in with perfect safety, from the fact that the manufacturer of cables, as well as the facilities for paying out at sea, have arrived at that state of efficiency, as to render success certain, and failure the trifling exception, oracularly held to prove all rules. It cannot well be otherwise, indeed, if the manufacturer is a skilful and practical man, the electrician honest, and all who have to do with subsequent operations are experienced in the work.

There was one point omitted, however, which, by some, may be esteemed of no trifling importance. That there is a great diversity of opinion as to the best form of cables for long deep sea telegraphs, and that, until this matter has been set at rest by practical means, in other words, by the proof which only a submerged cable will afford after having been in work a considerable time, the whole subject will necessarily engender doubt as to the prospects of success, of which we are so confident.

We are not disposed to treat this objection lightly, nevertheless we believe it to be the prolific parent of needless nervousness. The idea of heavy cables for such a purpose, if ever entertained, has been long since abandoned. All agree that a light cable, is not only sufficient, but the best, providing it have a specific gravity that will admit of its gradual descent to the bottom in a reasonable time. In fact, it is *strength*, not weight, that is required. It is simply, therefore, *the best form of light cable*, to which this apparently formidable difficulty is reduced, a problem, so easy of solution, as hardly to deserve the name of one.

There are many styles of light cables invented and patented, any one of which would be admirably suited to the purpose. Doubtless each has peculiar merits of its own, and, perhaps some of them, in the long run, would prove superior to the others; but they are all, more or less excellent, and, if any one of them were tried, we have no hesitation in saying that they would far exceed the expectations formed of them. We make this statement without the slightest reservation, save that the maker should be bound by contract to supply the whole equal in every respect to specimen; but this is presumed in all cases.

There are three main points to be studied in the choice of a light cable, to which we may briefly advert, premising that, if the one selected in any case should embody, in the greatest degree, these essential qualities, it will turn out to be the very best form of cable that can be made.

First.—It should be light, with a maximum of strength.

Secondly.—It should be of such a nature as to be proof against decay (comparatively), and the attacks of marine animalcules, should any exist at those great depths.

Thirdly.—The outer covering should be so applied as to ensure the greatest possible flexibility, without risk of elongation or kinks.

There are several light cables, that we know of, which fulfil these conditions; and, if there should remain doubt on the point of durability, it is easily set at rest by coating the whole with a specific compound, which, while it adds to its strength, is an effective preventive against the inroads of decay, and the whole tribe of gourmands, fabulous or otherwise.

We wish to give all possible force to this part of our subject, in order to restore that confidence in submarine telegraphic enterprise which should exist; not that we would foster a vain-confidence, or lead any person astray in so important a matter. We promulgate our views, and put forth our conclusions, because we have the best and most satisfactory grounds for them; for there is no one point on which we are more thoroughly satisfied, than that which the foregoing is intended to demonstrate.

In passing on to notice, briefly, the highly remunerative character of submarine telegraph lines, we feel that we have entered upon a work well nigh superogatory, since this is a necessary result of the first part. Very few will have any misgivings on this head, if they are satisfied upon the other. Happily, the most distrustful begin to see that failure, although it has been the rule, rather than the exception, is not a necessary consequence of such ventures. It is, however, a difficult task to enforce the conviction that the whole state of these matters will be inverted. It is far from easy to impress a man against his conviction, especially if such conviction has been produced by means which never fail to leave an indelible mark behind. An individual who has once lost, rarely has his faith resuscitated in similar projects, although it may be clearly demonstrated that he was a sharer in misfortune, by virtue of immatured experience, and all the evils which that, and overweening self-confidence entails.

We take our position, therefore, on the assumption of having proved the practicability of submarine telegraphy being an enterprise which, if due precaution be exercised, is no more liable to mishaps than other projects which absorb the attention of mankind, and, we are bold to say, has not more than an ordinary share in the chapter of accidents.

In order to show the advantages it offers to the mere capitalist it is not necessary to apply *couleur de rose*, and make it appear that a good cable will never wear out; that there will be no failures, no accidents, and so forth. We will take the matter upon reasonable grounds, and allow for wear and tear, for accidents, and all the train of ills to which things human are subject. Reckon that a new cable would be required every twelve years, as a rule, no matter what the locality, and it could easily be shown that, in even so limited a period, the receipts would far more than counterbalance the outlay, enable the company to pay a dividend rarely met with in these times, besides securing a reserve fund, for repairs, or resuscitation.

The history of the few submarine cables yet in existence, afford ample proof of this; and this is all the more remarkable when we consider that these lines were constructed at an enormous, and what, in a few years, will probably be deemed an incredible cost.

Making every allowance for the advanced cost of insulating, and other materials, which a demand for submarine cables will produce, it may, nevertheless, be safely calculated that future deep sea cables will cost, on the whole, considerably less than any cables yet submerged. This is easily understood, when we consider the defective method hitherto adopted for the various processes, and the vast expenses incurred in many ways, which we now see were wholly unnecessary. Add to this, moreover, that a good cable, securely deposited on the bed of the ocean, would be far more durable than we have taken credit for, seeing that both gutta-percha and india-rubber are improved by

submersion and pressure; and, assuredly, we are warranted in concluding that there is no enterprise of the present day that offers so large a return for the capital invested.

It is scarcely safe to indulge in the reflections of what might have been, had the Atlantic cable proved a success, and it had turned out capable of a moderate amount of work. Certain it is that the company would have been the wealthiest, and most powerful of the day. And it may be, even yet; nay, it is certain to be. No project of the time offers such vast advantages as that which connects two hemispheres, the commercial relations of which are to be valued at millions sterling annually.

THE INTERNATIONAL EXHIBITION, 1862.

(*Continued from p.* 19.)

3. *Instruments employed in the Transmission of Messages.*

These instruments have undergone many important changes. The needle, or galvanometer instruments spoken of with great approval in 1851, are still extensively employed in this country; but the Morse dot and dash instrument has been very largely adopted, and on the Continent is used almost to the exclusion of all other forms. At this moment, the old form of embossing Morse receiver is giving way before an ink-writer, printing the same code.

The acoustic telegraph, in which the signals are received by ear, first devised by Steinheil, and long neglected, is now in favour, and is used in India, America, and Great Britain. Relays have come generally into use, both to complete local circuits at receiving stations, and for the mechanical retransmission of messages from one section of the line to another. Many beautiful examples of these instruments are shown, and their use has been followed by a great extension in the capabilities of the telegraphic system.

To a limited extent various forms of dial step-by-step instruments are in use, and many excellent examples are shown, all more or less modifications and improvements of those exhibited in 1851. On the other hand, many instruments then thought worthy of reward have disappeared, without coming into practical use; and especially it may be remarked that none of the type-printing instruments then exhibited have been permanently adopted. Fresh ingenious forms are shown to effect the same object; may they be more fortunate than their predecessors!

Automatic transmitting instruments of great merit are exhibited; by their use increased speed, regularity, and distinctness may be obtained, and it is hoped that their adoption may allow messages to be sent at very low prices, and that, consequently, the use of the telegraph may be greatly extended. It is to be feared that this object will not be fully accomplished until the public prepare in some form their own messages for transmission, so as to reduce the functions of the company to a minimum. Now, the companies may be said to write each message twice over unnecessarily—once at the sending station with the transmitting key (and this would not be altered by the proposed use of punched paper or type transmitting-sticks), and once again after the message has been received. M. Bonelli's system, the lineal descendant of Bakewell's, alone of the automatic plans, dispenses with this second transcription; but M. Bonelli's plan cannot yet be pronounced practically successful. It is to be feared that, so long as this large amount of work is thrown on the companies' hands, the time saved by transmitting 400 or 500 letters per minute, instead of 100, will not justify any very great reduction of tariff, especially as the increase of speed must be accompanied by some loss of facility for interruption and interrogation. The success of the penny postage is frequently appealed to in favour of a low uniform rate, but the supposed analogy between the postal service and the telegraph is far from complete. In the one case the cost of transport hardly increases at all with the bulk transported; in the other case, after certain limits are passed, the cost of transmission increases almost in direct proportion to the number of messages sent. These limits depend on the number of messages per diem, which fully occupy the clerks and wires, and differ widely, no doubt, according to the system adopted. As improvements are gradually introduced the tariff will gradually be lowered, and the most sanguine anticipations may be realised; but no great sudden change could, in the writer's opinion, be effected even by the most ingenious apparatus exhibited.

Electric railway signals are shown, some of which are good practical instruments, and others are ingenious contrivances. The importance of this application of the electric telegraph to the protection of life can hardly be over-estimated; but it is probable that the simplest and most direct plans are the most to be depended on.

Messrs. Siemens & Halske, of Berlin, show the system adopted in many German towns for giving alarm in case of fire; and M. P. D. Prud'homme, of Paris, exhibits the domestic signals and bells now used in the Louvre Hotel, and other large establishments in France.

4. *Philosophical Instruments.*

The most important *philosophical instruments* connected with electricity are those by which the various measurements of electrical quantities are effected. These are four in number, each requiring its separate unit of comparison:—

1. Strength of currents;
2. Quantity of electricity;
3. Electro-motive force, or difference of potential, sometimes called tension;
4. Resistance of conductors.

The measurement of resistance has perhaps hitherto attracted more attention than that of the other electrical quantities; and resistance coils, based on different arbitrary units, are sent by exhibitors from France, Switzerland, Germany, and Italy, as well as by English makers. No two of those sent even from the same country are alike; a state of things attended with much the same inconvenience to electricians as would be felt by engineers, if every man chose the length of his own foot rule. Except those founded on the so-called absolute measure, none of the units have been chosen with any reference to the other electrical quantities, and still less with any regard to the units of force and work.

This is not a fit occasion to give a full account of the beautiful and coherent system of Weber and Thomson for the expression of these quantities in absolute units, chosen with reference to their relations with each other, and with the units of force and work which must henceforth be looked on as the connecting link between all physical measurements; but the leading idea of the system may be briefly expressed as follows:—

A battery, or other rheometer of unit electro-motive force, will generate a current of unit strength in a circuit of unit resistance, and in the unit of time will convey a unit quantity of electricity through this circuit, doing in the same time a unit of work or its equivalent. These relations leave the absolute magnitude of the series of standards undetermined. Weber has proposed to fix the series in various ways; but the most convenient (where measurements have to be made by observations conducted with the aid of magnets) is probably that in which the series is fixed by the definition of the unit current, as that current, the unit length of which at a unit distance exerts a unit force on the unit magnetic pole. The definition of the unit magnetic pole, proposed by Gauss and Weber, in its turn depends solely on the units of mass, time, and length. This admirable system, which cannot fail of ultimate adoption, is not yet so generally known as to have produced many instruments intended specially for its illustration or practical application.

Nevertheless, apparatus are exhibited which would, with more or less accuracy, enable every one of the required measurements to be made. Thus, tangent galvanometers are shown by various makers, and the absolute strength of current in the above units may be obtained from any one of them by the following formula:—

$$y = \frac{R^2 H}{L} \tan D,$$

where y = strength of current in electro-magnetic units,
D = deflection observed,
R = radius of the coil,
H = horizontal component of the earth's magnetism,
L = length of the wire composing the deflecting coil.

The quantity of electricity contained in any statical charge might be deduced with the aid of the make-and-break apparatus, or "Wippe" exhibited by Messrs. Siemens & Halske, by which a succession of charges are sent so rapidly through a galvanometer as to give rise to a constant deflection; from this deflection the strength of current may be calculated as above, and the quotient of the strength by the number of discharges per second will give the statical charge in the above measure.

Professor Thomson's electrometer gives direct measurements of potential or electro-motive force in arbitrary units, which can by a simple coefficient be reduced to the above absolute measure. The electro-motive force of a battery would be still more simply ob-

tained by multiplying together the absolute strength of current produced by it in a given circuit, and the absolute resistance of that circuit. The resistance coils exhibited by Mr. White, of Glasgow, were intended to represent decimal multiples of these absolute resistances, and these coils can be used for comparison, like any others, without reference to the principles which led to their original determination. These examples are given to show that the use of the above series of standards entails no special difficulty in the observations, and does not even require that the principles on which they are based should be understood by the observer.

The value to electrical science of a coherent system such as we have mentioned is very great; when generally adopted the results of independent observers all over the world will become comparable, and vague expressions of opinion will be replaced by definite measurements. Messrs. Siemens, Halske, & Co. exhibit an excellent arrangement for the comparison of resistances: their apparatus is based on Professor Wheatstone's bridge, or electric balance, as it might, perhaps, be better named.* No resistance coils were exhibited in 1851, although Professor Wheatstone's rheostat and resistance coils had been described in the "Philosophical Transactions" as early as 1843.

Two novel forms of galvanometer are exhibited—first, Professor W. Thomson's marine galvanometer, by which accurate observations of all kinds can be made at sea in all weathers; secondly, Gaugain's conical tangent galvanometer, by which he expects to secure a more perfect proportionality between the strength of the currents tested and the tangents of the angles observed.

Under the head of philosophical instruments may be included chronoscopes, of which it is to be regretted that none are shown by English makers. Professor Wheatstone published a description of the first instrument of this kind in 1840, and subsequently these instruments have received great attention from inventors in all parts of Europe. They have hitherto been chiefly applied to the measurement of the velocity of projectiles, a measurement effected by determining the time elapsing between the rupture of two wires placed in the path of the ball. Some idea of the perfection to which these instruments have been brought may be formed from the claim advanced both by M. Hardy and by Professor Gloesener, that by their instruments accurate results can be obtained at any part of the trajectory when the wires are only a yard or two apart. Improvement is, however, still possible in the methods used to obtain the perfectly uniform or constant motion required in the apparatus. Several forms of chronograph are shown for registering the instant at which an astronomical or other observation is made. The instrument exhibited by M. Krille, of Altona, appears to the writer especially meritorious.

Next may be mentioned the instruments used for the automatic regulation of the carbon electrodes of *electric lamps*. No less than eight distinct contrivances are shown for this purpose. Some more suitable for optical experiments, some for signals, and some for lighthouses, or similar practical applications. Faults might still be found with each instrument, but it is impossible to watch the quiet, steady flame of Mr. Holmes' light, or to see Mr. Serrin's lamp extinguished and relighted at a distance twenty times a minute by the simple interruption and re-establishment of the electric current, without feeling that on future occasions electric lamps will be classed rather among the practical applications of electricity than among philosophical instruments.

Induction coils of great merit are shown, by which currents of extraordinary intensity are developed in secondary coils of no extravagant length. These apparatus have acquired fresh interest from Mr. Gassiot's valuable researches. Tubes for showing the discharge in vacuo, and in various highly rarefied gases under a great variety of conditions, are exhibited by Mr. Ladd; many of these are made, however, in Germany. An electric resistance thermometer, a registering thermometer, and a current regulator, are novelties of considerable merit, and will be described in detail.

The great impulse given to the study of dynamic electricity by its application to the electric telegraph has somewhat diverted attention from statical phenomena. Mr. Varley, however, exhibits an interesting instrument for the production of statical charges of high tension and considerable quantity without friction or chemical action. This is effected by the direct transformation of mechanical energy into electrical effects by the intervention of induction alone. Fine samples of electrical machines with discs of vulcanite or hardened india-rubber are exhibited.

The want of a good meteorological electrometer, complained of in 1851, is remedied by Professor Thomson's portable instrument exhibited by Mr. White, of Glasgow. No improvements in permanent magnets or electro-magnets (unconnected with telegraphic apparatus) are shown, nor any novel apparatus connected with thermo-electricity. The University of Pavia contributes a collection of instruments now well known to all, but most interesting as having originally belonged to Volta.

(*To be continued.*)

* This is called by Professor Wheatstone the differentia resistance measurer.

BONELLI'S TYPO-ELECTRIC TELEGRAPH.

A very interesting meeting was held on Monday night at the offices recently taken by the Bonelli Company in Angel-court, Throgmorton-street. The object of the gathering was to witness the working, and discuss the merits, of the Chevalier Bonelli's beautiful system of telegraphic communication. The results must have been highly satisfactory to those interested, for it would be difficult to imagine anything more conclusive than the experiments, or more unanimous than the verdict given alike by amateur and professional spectators.

The instruments put into communication were two of the six originally constructed, one pair of which are at work between Manchester and Liverpool, the remaining pair being at Paris, where they are about to be placed—one at the Bourse, the other at the Great Central offices in the Rue de Grenelle.

The question of working with equal facility at a distance having been definitively put at rest by the experiments which have taken place between Paris and Boulogne, the proceedings of the evening assumed a position of importance and reliability wholly removed from the category of chamber experiments, and we are bound to say that the introduction of these instruments upon main lines promises to effect a complete revolution in telegraphic communication, such at least appeared to be the universal impression.

Throughout the evening the instruments were kept constantly at work, and without hitch, failure, or defect of any kind, the messages were transmitted and received with a rapidity truly wonderful.

The carriages were set to run their course in twelve seconds, and in this space of time a message was a thousand times over received and transmitted at and from each station; as the type boxes contain about thirty words each, it follows that these instruments are capable of printing with apparently unerring precision at the astounding rate of 18,000 words per hour; this, as the promoters consider it to be *slow* rate, is involved by the necessity of using for commercial work a solution which gives, under the action of the electricity, permanent marks. In transmitting press or other work, which has to be within a few hours set up in type or transcribed, the company propose to use the iodide of potassium; the decomposition of this salt is so facile, that the instruments would be able to print, in characters even more legible than those produced through the medium of the manganese, at the rate of 72,000 words per hour.

All the parts of the instruments appear simple and strong, and a very careful examination failed to detect anything which would convey the idea of delicacy or liability to derangement. The combs used were old in the service, and, we were assured, were rather better than worse for the work done. It is easy to understand that, with such a system, the proposed reduction of the price of each message of twenty words to sixpence may be found compatible with the interests of the shareholders, while it would be difficult to conceive that, even with such a reduction, any business can arise which would overtax the transmitting power of the machines.

We are thus promised the inestimable boon of cheap telegraphy eliminated from the too frequent drawbacks of delay and incorrectness.

Among the gentlemen present, whose numbers were doubtless, much diminished by the unfortunate locality and the inconvenient hour selected, were the following:—Lord Otho Fitzgerald, Dr. Smee, P. Le Neve Foster, Esq., Secretary of the Society of Arts; C. Le Neve Foster, Esq., F. N. Gisborne, Esq., W. Hall, Esq., W. Y. Dent, Esq., E. O. Brown, Esq., W. T. Henley, Esq., Frederick Purdy, Esq., R. Wills, Esq., J. L. Wheeler, Esq., Irving S. Taylor, Esq., F. Smith, Esq., Owen Rowland, Esq., W. D. Starling, Esq., James Figgins, jun., Esq., J. Spiller, Esq., Henry Cook, Esq., F. Faithful, Esq., B. H. Tindall, Esq., &c.

We are informed that it is intended to hold another meeting, and that any gentleman making a written application to Mr. Cook will be shown the instruments in operation.

TO ERECT A LINE OF TELEGRAPH.

(*Continued from p.* 17.)

THE following will be found a very useful form of survey:—

JANUARY, 1864.

Survey of proposed Line of Telegraph from Dipping to Cumberland Corner, being 18 miles per the Dipping railway, and thence by high road 10 miles, from Alloway Hill to Cumberland Corner. To consist of overground poles, carrying three English oak arms, respectively 22×2×2 inches, 20×2×2 inches, and 18×2×2 inches; compressed porcelain insulators, two single shed and four double shed, and the wire to be B.B. galvanized W.I., No. 8 B.w.g.; porcelain shackles, known as Bright's patent; binding wire, No. 16, &c., &c. The poles to be of good seasoned larch, with sound butts, not less than nine inches diameter, tapering to five inches diameter at the top.

Date of Survey.	No. of Stake or Mark.	Distance in yards.	Poles.			Arms.			Insulators.		Shackles.	Bolts, 6×½×½.	Wire.		Solder.	G. P. Wire.	Wood troughs.	REMARKS.
			18	24	30	18	20	22	Single	Doub.			8 Cwt.	16 lbs.	lb.	yards.	feet.	
1864. Jan. 4.	1					1	1	1			6	3	9	1	1	360	60	Start from Dipping Station:—1 *Standard*, 36×3×3½, English oak, to be fitted to booking office wall, with 2 *W.I. bolts*, 18×1×1. Leading, in boxing, to have 20 *clamps to order*. (Mem.—The wire allows for lightning conductors of No. 8 wire.)
	2	70		1		1	1	1	2	4		3						
	3	70			1	1	1	1	2	4		3						
	4	70			1	1	1	1	2	4		3						
	5	65			1	1	1	1	2	4		3						
	6	70			1	1	1	1	2	4		3						
	7	68	Cor	ner	1	2	2	2			12	6						Cross to opposite side of line over goods yard, straight.
	8	50	Cor	ner	1	2	2	2			12	6			1			
	9	70			1	1	1	1	2	4		3						1 *pitchpine Standard*, to be fixed to side of engine shed, 96×4×6, with 2 W.I. bolts, 18×1×1, and lead to order.
	10	70				1	1	1	2	4		3						
	11	70			1	1	1	1	2	4		3						Repair roof.
	12	70			1	1	1	1	2	4		3	9					On mound of cinders rising from level.
	13	68	1			1	1	1	2	4		3						Direction of line—
									&c.	&c.	&c.							
Jan. 7.	451	100	Cor	ner	1	1	1	1			6	3	9	1	1	720	300	Reach Cumberland Corner, and pass underground to Alloway Hill, 100 yards. 1 *cwt. Stockholm tar, and 50 lbs. pitch*, to order.
	452	60				1	1	1	2	4		3						
						&c.		&c.		&c.								
Total Length																		1 *Standard, English oak*, 36×3×3½, *with* 2 *finials*, to be fixed to wall of Mr. Briggs' house.

The following will be found a very near approach to an estimate for such a line:—

	£	s.	d.
79 poles, 18 feet long, each, 5s.	£19	15	0
50 " 24 " " 7s.	17	10	0
550 " 30 " " 10s.	275	0	0
25 standards, pitchpine, each 96×4×6, 5s.	6	5	0
25 wall pieces, English oak, each 36×3×3½, 6½d.	0	13	6½
679 earthenware polecaps, 4d. each	11	6	4
75 finials, 6d. each	1	17	6
739 arms, English oak, 18×2×2; ditto, 20×2×2; ditto, 22×2×2; say 2,217 arms, at 3d. each, planed and bored to order	27	14	3
2217 W.I. bolts, 6×½×½, as per pattern; say 15½ gross, at 12s.	9	6	0
1446 single shed porcelain insulators, with W.I. pins and nuts, 6d. each	36	3	0
2892 double ditto ditto 1s. each	144	12	0
96 porcelain shackles, 1s. 6d. each	7	4	0
26 tons No. 8 B.B. galvanized iron wire, at £19 10s.	507	0	0
40 lbs. No. 16 galvanized iron wire, at 3d.	0	10	0
20 lbs. best solder, at 9d.	0	15	0
2 miles No. 16 copper wire, covered with No. 8 gutta-percha, at £24	48	0	0
420 feet wood boxing, 2×2, with 1-inch groove, and lids, at 3d.	5	5	0
Sundry iron work, including extra sized bolts	2	0	0
Pitch and tar	1	12	0
Repair of roofs, including lead	2	0	0
Stripping, dressing, and charring 679 poles; each to have a red ring drawn round it, six feet from the butt, at 1s. each	33	19	0
Carriage of goods, carting, and laying out stores	9	0	0
Labour:—1 Foreman, 12s. per diem; 2 carpenters, 6s. do.; 3 linemen, 6s. do.; 12 labourers, 3s. 6d. do.; 3 boys, 2s. do. 21 men, earning, jointly, £4 10s. per day, for 28 days	126	0	0
Painting, *by contract*, 729 poles and standards; poles to be tarred; two good coats of tar 12 inches under the surface, and four feet above the ground; the rest to have two good coats of stone paint. The standards to have two good coats of stone paint. 2s. each	72	18	0
Railway fares, and travelling expenses	4	10	0
Sundries	2	0	0
Supervision	68	12	6
	£1,441	8	1

Thus it will be seen, by this estimate, that a line of six wires, erected in the most substantial manner, and finished in such a way as to stand for twelve or fifteen years, and including the supervision of a professional telegraph engineer, may be provided at a cost of about £51 10s. per mile. No doubt men could be found who would undertake the work for a less sum, but it is very questionable if a perfect working line, such as a telegraph line should be, can be erected cheaper. One item, that of tools, is omitted. Every carpenter finds his own tools, every labourer his own pick and spade, and, as the tools required by a telegraph lineman are not expensive, and his wages are calculated at the same rate as a carpenter's, it is considered as an equivalent, and that it is time the trade of a telegraph lineman should be regarded as a distinct calling, and thus render it unnecessary for telegraph companies to invest any part of their capital in tools and kits. Of course it is equally desirable that the lineman's wages should be calculated on the same principle as that of the carpenter, stonemason, or any other trained workman.

For the maintenance of such a line, the cost is easily calculated. It is erected with a view to lasting fifteen years. Divide, therefore, the total sum, and it will be found that the annual cost of the line will be less than £2 per mile. For the first five years there should be no charge whatever upon it, save for one course of tarring and painting, an item that figures in the estimate for £72 18s.

It is necessary to recommend that the larch trees for poles should be felled in the winter, the sap is then out of the wood, and the timber harder, and more durable. It will take a little longer to dress the pole, but that is allowed for in the charge. Take care that the pole is turned out as smooth as it can be, and that no knots or swellings are allowed to remain.

The object of the red ring, which we believe was first adopted by Sir Charles Bright, is simply to save trouble in examining the poles when set in the ground, as it is then easy to see that each has been placed a sufficient depth. The stores having been sent forward, and paid out according to the survey, a copy of which should be given to the foreman, the gang may go to work.

The men to dig out the holes go first, three pairs (men always work best in couples), and one lineman takes the six men, as also the two carpenters, who fit the arms, insulators, polecaps, and lightning conductors, erect the standards, and render any help that may be required in rearing the poles. Avoid fixing poles to

the bridges of railways, they are better in the earth, and more likely to stand severe weather. If attached to brickwork, and they rock at all, they will be sure to bring a parapet down, and the consequences to the company you represent may be serious. This gang of nine men may have one boy, and the lad will soon prove that, in his way, he saves a man's wages.

It is a good plan to fix the poles for a month before the wiring begins, but, with careful men, any fear of unsteady work is avoided, and we will therefore suppose that, as the poles are set, the wiring gang prepares to follow; this gang includes the two linemen, six labourers, and two boys. The jointing of the wire should never be left to a labourer; it is a lineman's duty, and by far the most important one. In running six wires, the lineman will want the help of a labourer, for the purpose of holding the wires to be jointed, while the boys take the firepots, &c.; but it is the lineman, and the lineman only, who must bind the joint, and apply the solder, and it is well that the foreman should keep an occasional eye to seeing that these are done with care, and not hastily. We prefer the Britannia joint to any other in use.

The wire should be pulled up by blocks; this prevents the jerking that breaks so many insulators. When it is pulled up to its full tension, it should be slightly released, and this will allow it to contract or expand, as the weather becomes colder or warmer. When fastened down to each insulator by the binding wire, the arm should be carefully examined, to see if the strain has shown any sign of weakness in the arm, insulator, or bolt, and if so now is the time to apply the remedy.

Should any strain lead the foreman to consider it requisite that a guard should be placed over the wire, he will order it to be done. It is a matter for consideration if it be not advisable to place a guard over every insulator, and, certainly, for work along high-roads, or round railway curves, it is only a proper precaution. They can be procured for about 3d. each. In this manner the line will soon be completed. The terminations of the wires should then be placed to air, and each one carefully tested. If a wet day can be taken advantage of, all the better, and the slightest loss should be sought out by the foreman. As soon as the line is reported in writing, by the foreman, to be electrically perfect, the engineer will inspect the works, and test the wires, and then, if handed over to the party for whom it is erected, under the written certificate of the engineer himself, there can be no difficulty in placing the responsibility on the shoulders of the proper party.

It is not unlikely that we shall meet with some unfavourable comments upon our advice on this subject. Our calculations may be wanting, or they may be too high. We can only repeat, that a good line is the cheapest in the end, and that the telegraph companies, at the present time, fully recognise the necessity of exercising the greatest care in the construction of their works. Every insulator should be tested before it is erected, and if found, however slightly, in fault, it should be rejected, for that fault will increase, and give rise to many intermittent faults, if allowed to go on the work. But the insulator will form the subject of another paper; meantime Mr. R. S. Culley's work is one, that if for this section (insulation) only, should be in the hands of every telegraph engineer.

ON TIME AND TIME-GUNS.

THE Report of the Astronomer-Royal for Scotland, lately read before the Board of Visitors of the Calton Hill Observatory, calls attention to a subject of great and growing interest which, for some reason or another, is rather strangely overlooked by us Southrons. We allude to the question of correct time-keeping. It, indeed, is more than strange that in this London of ours especially—where, above all other places in the world, time is money—the true time is scarcely to be had.

It has been well said that we can arrest the flow of time by continued motion, and, by journeying faster than light, actually travel into the past again. The London clocks, however, lessen the difficulty of this feat, for the time once gone—the old proverb notwithstanding—oft returns, and is repeated by lying tongues from a hundred steeples, in spite of the warning tone of Big Ben, which, on the Astronomer-Royal's authority, we can point out as a brilliant exception; albeit one arrived at by much labour, seeing that an attendant receives a signal from Greenwich once *every hour*, and the clock reports its state to Greenwich twice every day.

The eminent men in charge of our national observatories are as ready and willing to "lay on" time to our towns as they are to our coasts. Thanks to their labours, the noble problem of finding the longitude at sea has now been solved with a perfection which leaves nothing to be desired. It is possible now to calculate the place of the moon for years to come with a precision which shall surpass that with which a single instrumental observation can be made of it. So that, in fact, unless we improve our time-keeping on shore, the mariners will be ahead of us.

We have before alluded to the magnificent conception which is now being carried out in Paris. So far back as 1852 M. Paul Garnier suggested the establishment of a normal clock, electrically connected with others, which the current should drive and regulate. At the present moment M. Verité, who has reduced the question of electrical regulation to one of great simplicity, is applying it to all Paris. A transit instrument is to be erected in the Tour St. Jacques, where meridional observations will be made and the normal clock installed. Four dials on this noble tower, *furnished with seconds-hands,* will show the time, which electrical currents will give to seventeen other principal clocks, similarly furnished—these in their turn regulating all the other public clocks of Paris. So much for correct time-keeping *à la Française.* In our account of the British Association we described the method adopted in Scotland, and many who have not yet crossed the Tweed had occular and audible demonstration of it at the meeting at Newcastle, when at one o'clock the true time was proclaimed by cannon from the commanding top of the fine old Border Castle, in its turn o'ertopped by the world-renowned "High Level."

Professor Smyth, in his report, tells of the extension now being given to this eminently practical system. Since the Newcastle meeting, when it was in operation both there and at Shields, and was fully appreciated both by seamen and landsmen, Sunderland has applied, and has now its permanent time-gun. Several other cities have followed suit, and the local negotiations for the means of loading their respective guns are in different states of forwardness, the only one which has at present succeeded in perfecting its arrangements being Glasgow, the Queen of the West. Professor Smyth writes:—

"The Edinburgh Observatory dropped a model time-ball daily for a week by electric means in a public meeting-room of the Glasgow College in the year 1855. That work was successfully performed, besides its principle having been formally approved; but somehow there was not enough in the time-ball system itself to fully interest the practical inhabitants of the great western city. When, however, after eight years had elapsed, and the inventions of Professor Wheatstone had enabled an electric current to explode a distant gun more easily as well as certainly than to drop a ball, and the citizens of Glasgow did locally provide a cannon, and, aided materially by the well-known Magnetic Telegraph Company, did connect it by wire with the Edinburgh Observatory, and when the current from there did consequently discharge the Glasgow gun simultaneously with the several guns of Edinburgh, Newcastle, and Shields, the strong common sense of Glasgow's citizens immediately perceived the superior efficiency of the new system; for, after a week's experiment with from 2 lbs. to 2·5 lbs. of gunpowder a day, from a cannon temporarily placed, as will be seen in a schedule recently received from them, they are now vigorously adopting a new and more suitable locality, with the noble charge of 8 lbs. of powder, or nearly double of what is used at any of the other stations."

In our number for the 24th of January last we gave an extract from the *Scottish Society of Arts,* showing that the Edinburgh time-gun is actually regulating the clocks within a radius of some sixteen miles. Of what incalculable advantage must this be both to employer and employed! Why are we not as well off in London as they are in Scotland? or, indeed, in Liverpool, where, thanks to Mr. Hartnup, who prefers the Parisian system, there are many controlled clocks, and where, it would seem, there is such a superabundance of the true time, that Mr. Hartnup has volunteered time-signals to London—to our shame be it spoken! Let us, *en passant,* mention that, on the 4th of February, 1861, between six a.m. and five p.m., one thousand eight hundred and sixty persons compared their watches or chronometers with one of Mr. Hartnup's controlled clocks.

Greenwich is by no means behindhand in fostering this good work; but at present London is slow to appreciate its value. From the Royal Observatory time-signals are sent daily along the principal lines of railway, even as far as Glasgow and Cardiff, and *many private companies through whose offices the wires pa[illegible] have begun to distribute branch signals to private factories.* At the [illegible] at Aldershot, where, we believe, one of these signals is received, [illegible]

time-gun has lately been in operation, although it is fired by something less ethereal than electricity.

It is a thousand pities that the Westminster clock, which we learn on such excellent authority keeps true time, has its value so seriously impaired by the absence of a seconds-hand. It may be urged that there are many clocks in London so furnished. True, but we pity the luckless wight who shall put his faith in them. We have known many instances where a journey to Greenwich has actually been performed when time true to a second has been required; for we regret to say that the Harrison clock of the Astronomical Society, which ought to show true time, and did a little time ago, has left off doing its duty. The Astronomical Society has in this matter lost an opportunity of doing good work.

Let us conclude by expressing a hope that either Professor Smyth's or M. Verité's method may soon be introduced where certainly it is most wanted; let us not be content in this metropolis to be behind Paris, or even our own provincial towns and private factories. M. Verité's arrangement commends itself at once to all. The following extract from the last published volume of the Edinburgh *Astronomical Observations* will show us the great practical value of the former method. A combination of both of them would best suit London.

Professor Smyth, after referring to the time-gun system, remarks:—

"Thus much, then, for the *idea*, and next, on the experience of nearly twelve successive months, we can add that the *practice* of this audible signal has answered to admiration in almost every point. For instance—1st. It has never given wrong time yet, by any accidental discharge before or after the intended time, even to a fraction of a second. 2ndly. It is so remarkably prompt in its action that there is absolutely, and to the most refined observation no sensible retardation between the striking of the tick of the sixtieth second by the normal clock in the Observatory and the visible gun-fire at the Castle. This result, which is superior to that which occurs with the time-ball by about 0·14 of a second, the amount of constant retardation observed there, is produced by a peculiar compensating action in the controlled clock at the Castle, whereby the trigger of the gun is pulled at such a fraction of a second before one o'clock, that the explosion takes place exactly at one. 3rdly. No inclemency of weather, as rain, frost, or snow, or wind of any strength and from any direction, has ever interfered with the regularity of the gun-fire; and this speaks well, not only for the manner in which electricity is employed to do the work required of it between the Castle and Observatory, but also for the soldiers at the Castle told off to the duty of daily loading the gun, and often having to perform it under circumstances of such extreme wet and discomfort that, unless they exercised much care and skill the igniting quality of the powder might easily be affected. In fact, since the 7th of June last year, there is only one proved weak point in the whole arrangement; and that is, the quality of the friction fuses, which are prepared by, and furnished from, the Royal Arsenal at Woolwich; for one bad fuse—that is, one which does not go off at all, and therefore causes no gun-signal to be heard that day—is still occasionally met with amongst a large number of good ones."

Let us hope that before very long the maps of London shall contain those red concentric circles which already distinguish those of Edinburgh, Newcastle, and Glasgow.

We reprint the foregoing article from the *Reader* at the request of an esteemed correspondent.

SOCIETY OF ARTS.

Wednesday, December 10th, 1863.

DR. W. A. MILLER, F.R.S., IN THE CHAIR.

ON MAGNETO-ELECTRICITY, AND ITS APPLICATION TO LIGHT-HOUSE PURPOSES.

By F. H. HOLMES, ESQ.

As this is a paper on the application of Magneto-Electricity to lighthouses, I will begin by saying a few words on lighthouses themselves, their former and present state, and the systems now generally followed in the arrangements for lighting.

Formerly lighthouses were very few, and were nearly all coal fires on high cliffs or towers, and most of them were the property of private individuals; but, as shipping increased, so the lighthouse system became more and more developed, both in the number of lighthouses and in the improvement of those already existing. The coal fire gradually gave way to the oil lamp and candles; next we find the introduction of spherical mirrors or reflectors, and these, again, were superseded by parabolic reflectors, sometimes to the number of more than thirty in one lantern. After this came the introduction of the "Fresnel Lens," which took the place of the reflectors and their lamps, however numerous they might be, and required instead one central lamp.

This "Fresnel Lens" has again grown, so to speak, larger and larger, as the want of a more powerful light was felt, till it has now a diameter of 6 ft. and a height of 10 ft.—for to increase the quantity of light the size of the lamp must be increased, and the lens in proportion, or it would have been so far out of focus that the intention of the lens would have been frustrated.

To make these progressive improvements in lighthouses, vast sums of money had to be expended; and now let us see what was the end sought. First to improve the light itself. This is done by the substitution of a lamp of four concentric wicks, the largest nearly 4 in. in diameter, for the coal fire. If the improvement had stopped at that it would have been small indeed, but this lamp is more under command than the coal fire. The value of the introduction of oil is not so much then on account of its greater power, as for its aptitude for the employment of economising apparatus, whether this consists of reflectors or lenses. All incandescent bodies give out rays, as it were, from the centre to the circumference of a sphere; of such rays only those which fall on the sea would be useful to the mariner, but by means of reflectors those rays which would pass inland, or upwards, or downwards, are reflected towards any required point, and by a proper arrangement of a series of reflectors, the whole, or nearly the whole, of the rays are directed where required. The Fresnel Lens consists of a middle refracting belt, and a double series of reflecting prisms, or zones, as they are generally termed, and when properly constructed it has the property of collecting all the rays into one horizontal beam, so that all the light from the lamp is utilised. Thus, then, we see great strides have been made since the introduction of oil lamps, as regards the lenticular apparatus—in fact, that may be said to be nearly perfect; let us then return to the consideration of the light itself for a moment.

Whether a large or a small lamp be employed it will make no difference in misty weather, so long as the thickness of the flame is the same, for a large lamp may be equal to ten or twelve smaller ones, and if replaced by these ten smaller, it will be evident that when one of these is obscured by mist, the whole of them will be obscured. Quantity of light then will not add to its power of penetrating mist. By making the large lamp with four concentric wicks the intensity of the light is a little increased, and such a lamp will penetrate further through mist in a slight degree. But it is in misty and hazy weather that the light is most required; hence, now that everything else is nearly perfect in a lighthouse, the authorities, both in this country and elsewhere, are directing their attention to the only thing wanting to make the whole system perfect, that is a light capable of penetrating mist; and as this power depends on the intensity of the light, and electricity is capable of producing the most intense light known, it was naturally looked to as the possible means of perfecting the whole system. But the light produced by electricity to be applicable for lighthouses must be certain and constant, not liable to extinctions or any great variations, as the first would tend to endanger vessels seeking and not finding the light; and if a fixed light had much variation, it might be mistaken for a revolving light.

Let us now see whether electricity can produce a constant steady or uniform light. Frictional electricity will give a succession of flashes intensely vivid, and might be used for the purpose, but for the fact that the slightest moisture is sufficient to convey the whole charge to the earth. The various forms of galvanic battery are all capable of producing a steady and intense light, but still (besides the great expense) they are not applicable, because of the necessarily varying current, which becomes weaker and weaker as the solution becomes saturated. The magneto-electric machine is then the source from which one would naturally expect a light which should be invariable in its nature, and capable of being continuous for any given time, as the current produced by this machine is constant as long as the helices revolve with the same speed, and the speed can be easily regulated to any required velocity.

The electricity derived from a magneto machine is induced in coils of wire, by the changing of the magnetic polarity of pieces of soft iron enclosed within the coils of helices; and the quantity or intensity of the induced current depends, first, on the amount of magnetism induced in the soft iron; secondly, on the facility with which the poles of the magnetised soft iron can be reversed; thirdly, on the velocity with which the change of polarity takes place; fourthly, on the length and diameter of the wire forming the helices.

The amount of magnetism induced in the soft iron depends on the size and force of the steel magnets employed, and on the weight and softness of the iron in the helices; but the weight in practice of the soft iron is limited by the weight of the steel magnets, for, if too heavy, the steel magnets will be slowly deprived of their magnetism. To facilitate the change of the poles, the soft iron cores of the helices are not solid pieces of iron, but are tubes, single, double, or treble, as it is found by experiment that the same weight of iron, when divided in this manner, loses or takes magnetism in much less time than when in a solid form.

There is a limit to the velocity to be employed when the maximum of electricity is required, for this reason. It has been already remarked that the amount of electricity depends on the amount of magnetism taken up, and that the soft iron takes time to become saturated, as it may be termed, with magnetism; hence, if the velocity be too great with which the cores move from one pole of a magnet to another, there will not be sufficient time for the cores to become saturated. But as, again, the quantity of electricity increases as the velocity increases, it is necessary to ascertain this maximum point exactly, which is easily done, either by experiment or calculation, based on certain data. The length and diameter of the wire require to be different, according to the current required; for a short thick wire, forming the helices, represents a galvanic battery composed of a dozen, say, of very large pairs of plates, whilst a long thin wire would represent a battery composed of thousands of small plates. In other words, supposing the size of the helices to remain the same, if they are composed of thick short wires, quantity is obtained; but if composed of long thin wires, intensity will be the result.

From all this it results that there are certain laws known and established, by which a magneto-electric machine can be made to give a current of any given amount of electricity, with any given ratio between its quantity and intensity.

Having seen on what the production of the current depends, the next point to observe is the peculiar nature of this induced current. It differs essentially from a galvanic current in this, that while the helices are revolving, the direction of the current is reversed, as the core of soft iron passes each consecutive pole of the steel magnets.

It now remains to explain how the current generated in the wires of the helices is to be withdrawn from the machine. In the first place all the helices are connected in two, or four, or more series; in doing this, great care must be observed that the direction of the coil of every alternate helix is in an opposite direction, that is, if one is wound as a right-hand screw, the next should be as a left-hand screw, or, what amounts to the same thing, supposing all wound in the same direction, then the two inner ends of the wires must be joined of, say, Nos. 1 and 2, and the two outer ends of the wires of Nos. 2 and 3, and so on through the series; and lastly, the terminals of the series might be soldered into two insulated discs, and then led from the machine by two pieces of metal kept in contact with the outer surfaces of these discs by a slight spring; such an arrangement allows the alternating current to pass from the machine, and such a current will produce a light, but this light has certain disadvantages. It is never white, but always more or less blue or brownish; in fact it is like the electric light obscured by placing it behind a flame from spirits of wine. It is also extremely injurious to the eyes, both from its colour and its tremulousness; I therefore do not use this current, but in its stead I convert this constantly-inverting current into two that flow from the machine in one direction only. This is accomplished thus: one half of the helices are arranged so as to arrive on the poles of the magnet at the instant that the other half are exactly midway between the poles. Thus there are two distinct currents; and what may be called the dead point, that is, the point when the current inverts in one series occurs exactly at the time when the other current is at its maximum, so that if now the inverted currents can be again inverted in both of these distinct currents, and that the two now flowing in one direction can be united as one compound current, it is evident that the result will be a current nearly as uniform as that from a galvanic battery, with the advantage of equable continuity. This is done by the two commutators, which consist each of two insulated rings of metal, of such a form at the periphery that two rollers or rubbers change sides from one disc to the other at the same instant that the current is reversed. Then, by combining the two commutators, a compound current is obtained that will produce a constant white light, or perform any of the other functions of the galvanic current, and in a more perfect manner, as it is more uniform in its action.

A steady and constant current thus obtained from the magneto-electric machine is only one part of the problem of producing a constant and steady light, and, although the most important part, still it would be perfectly useless without an efficient lamp or regulator. In order to understand this it is necessary to explain that the carbon points used for producing the light, or for converting a portion of the electric current into light, are consumed, and that the rate of consumption is irregular, owing to the irregularities in the structure of the substance used, which is the kind of graphite deposited in the gas retorts sawed up into pencils about a quarter of an inch square; but as the consumption is irregular, no clockwork with continuous motion could be employed for the purpose of causing the carbons to approach as consumed, for it must be understood that the steadiness of the light as well as its brilliancy depend on the two carbon points being maintained constantly at a certain distance corresponding to the strength of the electric current.

Many pieces of apparatus more or less complicated have been invented from time to time, for the purpose of regulating the movements of the carbon electrodes, and many of them I have tried, but none of them, as formerly constructed, could be used in a lighthouse, because they were more or less uncertain in their action, and because the clockwork was too delicate and liable to accident in other hands than those of an electrician. The question, what constitutes a good regulator, must be answered by stating what it must accomplish; and, moreover, it must perform its several functions in the most simple manner. It must, in the first place, maintain the carbons at a given distance, whatever be the variation in the state of consumption, and must also be capable of being adjusted to any strength of current; secondly, if by any accident the current should be interrupted, and the light thereby extinguished, the regulator should be capabe of relighting at once with full brilliancy, that is, not only must it allow the carbon points to touch to re-establish the current, but must separate them again instantly, or there would be no light. Such a regulator we have here, for its construction is simple, and it performs its different functions in a most perfect manner. Its construction is this: the upper carbon is attached by a kind of small vice to a bracket, standing out from a tube, which slides freely in a column. The lower carbon is fixed in the end of another tube, exactly under the other carbon. Both of these tubes are put in motion thus: two cords, passing over pulleys, properly arranged, are wound on one spindle, but in opposite directions. On turning a stud fixed on the end of the spindle, the regulator is wound up; that is, the top bracket is raised, and the lower tube depressed. On removing the hand from the stud, the upper tube would descend, and, being loaded, would cause the lower tube to rise; but to prevent this, while the regulator is out of use a bolt is pushed in, which prevents any movement in the regulator till it is again withdrawn. The regulator being wound up, the carbons are firmly fixed in their places by tightening the holders, and are then adjusted so as to bring the points in the focal plane by turning a spindle to which the fixed end of the cord belonging to the lower carbon is attached.

So far the regulator is only a means by which the carbons can mutually approach each other with a certain relative speed, depending on the different diameters of the two parts of the spindle around which the cords are wound. But if the carbon points remain in contact, there will be no light. Some contrivance, then, was necessary to separate the points to the distance, which, by experience, is found to give most light, and to maintain that distance between the points constantly till the whole of the pair of the carbons is consumed. These two operations are accomplished thus: the fixed end of the cord which works the upper carbon is attached to one end of a lever; the other end of the lever has a piece of soft iron attached to it, over an electric magnet, so that when the bolt is withdrawn and the carbon runs together until they touch (thus allowing the current to pass) this electro-magnet instantly, by the action of the same current, lifts the cord, and with it the upper carbon, to the required distance. But this is not all, for the carbons would again run together were there not some contrivance to prevent them. To accomplish this, advantage is taken of these two facts—first, that the quantity of electricity is proportional inversely to the distance between the carbon points; secondly, that the strength of an electro-magnet is proportional to the quantity of electricity passing through the wire that surrounds it. Bearing these two facts in mind, it will be easy to understand the use of the second electro-magnet. Over this electro-magnet, at a small distance above it, is placed a lever, one end of which is drawn down by a spring, the strength of which can be regulated by a thumb-screw. The fulcrum is between this end and the centre. The

other end of the lever is furnished with a catch, and immediately over the electro-magnet a piece of soft iron is fixed in the lever. On the carbons being allowed to touch as before, not only are they separated by the means described, but this second lever, acted on by its electro-magnet at the same instant, is drawn down towards it, and thus brings the catch between the teeth of a wheel placed under it for the purpose, and effectually locks the regulator. The strength of the spring is now adjusted till its tendency to lift the catch out exactly balances the current which draws it down. Should the distance now increase but the $\frac{1}{500}$th of an inch, the spring will be stronger than the current, will lift the catch, and the carbons will approach; but by doing so more current passes, the electro-magnet is strengthened, and is again enabled to overcome the spring and draw down the catch, and thus by their mutual action the distance between the carbon points is all but invariable.

When these regulators are employed in a lighthouse there are a pair for each lens and two small lenses, so that although it may take ten minutes to replace the consumed carbons, still the light is never extinguished; for, suppose the carbons consumed in the lens No. 1, the regulator is ready in lens No. 2; and all the light-keeper has to do is to bolt the No. 1 regulator, and draw the bolt of the regulator in No. 2 lens; the current is thus diverted, No. 2. is instantly lighted, and the lighting of this extinguishes No. 1.

Thus, then, we have a most intense light, which may be maintained for any length of time, which does not require to be trimmed or extinguished for a second, and which has all the steadiness and uniformity required for lighthouse purposes. Its advantages over the oil lamp are—first, its power can be increased *ad libitum* without increasing the size of the lens, for, if required, a machine may be made to give light enough to read by, say, at ten or twenty miles; in fact, the light is in direct proportion to the power of the machine that produces it: secondly, its great intensity gives it a power of penetrating haze only equalled by the sun: thirdly, its whiteness distinguishes it most perfectly from all other lights on shore, which is one of its most important properties, for many a vessel has been lost for want of this property in lighthouses lighted with oil: fourthly, where coloured lights are required, for the purpose of distinguishing one lighthouse from another, this light gives all the colours in a perfect manner, while the oil lamp always gives its own tinge to the colour employed: fifthly, from the facility with which this light can be extinguished in an instant, and as instantly lighted to its full power, it offers other means of distinguishing lighthouse from lighthouse, which cannot be obtained with any other light. The importance of this may be understood from the fact that there are still many points around our shores that require lighthouses, but which must remain without them till better means of distinguishing them with certainty from others in the immediate neighbourhood can be employed; for having no lighthouse is hardly worse for the navigator than having two in sight which cannot be distinguished one from the other.

An objection has been made to this light, that, being so small, it would be altogether invisible at a considerable distance; and when we merely consider that the apparent size of distant objects depends on the visual angle, there seems to be some ground for the objection, but the law of visual angles does not apply in the case of self-luminous bodies, as can be demonstrated with this piece of fine wire, which, I suppose, is almost invisible, even with a strong light thrown on it, but now, if, by passing a current of electricity through it, it is made self-luminous, it appears gradually to increase in diameter as it becomes brighter; and as a curious fact, illustrating the difference between the theorist in his study and the practical observer, a sailor, who had seen the magneto light from a great distance, told me he supposed it must be at least ten feet in diameter. Another objection to the light is, that it is too bright; this may be an inconvenience in clear weather, but a light to be useful when most needed must be inconveniently bright in clear weather.

The last point to be considered is the cost of the magneto-electric light as compared with oil. The French director-general of lighthouses has made a report to his Government, both as to first cost and as to cost of maintenance; both are greatly in favour of the magneto-electric light: of course in making their calculations of cost, they take the cost of an equal quantity of light in each case, that is, by oil and electricity.

I have now only to remark, that this invention, if it may be called one, is purely English. Faraday commenced it when he discovered the fact that magnetism might be made to produce or induce an electric current; and although the magneto-light was first produced in Paris, it was by me; and so far from receiving assistance from any of the French *savans* in the matter, I was ridiculed by all of them for attempting what they said they could demonstrate was impossible. With regard to the regulator, which is also invented by me, there is another just invented by a Mons. Foucalt, on a very different principle, but which is quite as effective, though overloaded with clockwork. His regulator has this peculiarity: it can be used in a rolling vessel, and will bear with impunity the vibrations of a steamer.

METEOROLOGIC TELEGRAPHY.

MANY of our readers are, perhaps, not aware of the assistance the wonderful *forecasting* department of the Board of Trade derives from our telegraphic system. We quote the following interesting description of the services rendered from Admiral FitzRoy's new work, the "Weather Book:"—

"As an example of what has been done in this direction recently, under the auspices and by the powerful means of Government, authorised by Parliament, a brief *outline* will now be given of the practical system established at the Board of Trade with reference to Meteorologic Telegraphy: of its history, and the methods of present application; after which the more *difficult* parts of these subjects will be further treated—namely, their actual management in daily practice, the various conditions and circumstances under which the ever-changing states of atmosphere occur, and full explanation of the reasons for such decisions as are made in forecasting weather.

"In meteorology some degree of increased interest has been caused, not only by various discussions and publications, but by this organised system of forecasting weather, and giving cautionary notice of expected storms.

"In treating so complicated and extensive a subject as that of our atmosphere and its movements, it is extremely difficult to combine mathematical exactness with the results of experience obtained by practical ocular observation and much reflection; but to some extent this has been effected recently, the Board of Trade having arranged telegraphic and frequent communication between widely-separated stations and a central office in London, by which a means of *feeling*—indeed one may say *mentally seeing*—successive simultaneous states of the atmosphere over the greater extent of our islands was established, and an insight into its dynamical laws has been obtained, to which each passing month has added elucidation and value.

"Possibly at this time, when extensions of our arrangements to the Continent are established in France, and will be in Hanover and Prussia (although *here* there are still persons who doubt their utility), it may be desirable to give an explicit description of the basis, and the nature of the forecasts and occasional warnings which have been proved useful repeatedly during the past two years.

"The first cautionary or storm-warning signals were made in February, 1861, since which time similar notices have been given, as occasion needed.

"In August, 1861, the first *published* forecasts of weather were tried; and after *another* half-year had elapsed for gaining experience by varied tentative arrangements, the *present* system was established. Twenty-two reports are now received each morning (except Sundays), and ten each afternoon, besides five from the Continent. Double forecasts (*two* days in advance) are published, with the full tables (on which they *chiefly* depend), and are sent to eight *daily* papers, to one weekly, to Lloyd's, the Admiralty, the Horse Guards, the Board of Trade, and the Humane Society.

"The forecasts add almost nothing to the pecuniary expense of the system, while their usefulness practically is said to be more and more recognised.* Warnings of storms arise out of them, and (scarcely enough considered) the satisfaction of knowing that no very bad weather is imminent may be great to a person about to cross the sea. Thus their negative evidence may be actually little less valuable than the positive.

"Prophecies or predictions they are not; the term forecast is strictly applicable to such an *opinion* as is the result of a scientific

* At a meeting of the shareholders of the Great Western Docks at Stonehouse, Plymouth, it was stated officially that "the deficiency (in revenue) was to be attributed chiefly to the absence of vessels requiring the use of the graving docks for the purpose of repairing the damages occasioned by storms and casualties at sea." (In 1862.)

combination and calculation, liable to be occasionally, though rarely, marred by an unexpected "downrush"* of southerly wind, or by a rapid electrical action not yet sufficiently indicated to our extremely limited perception and feeling. We shall know more and more by degrees. At present it is satisfactory that the measures practised daily in these proceedings do not depend solely on any *one individual*, but are the results of facts exactly recorded, and deductions from their consideration, for which rules have been given. An able assistant shares their responsibilities *now*, and others are advancing satisfactorily in the study of dynamical meteorology."

INDIA TELEGRAPH DEPARTMENT.

COMPETITIVE EXAMINATION OF CANDIDATES FOR APPOINTMENT AS INSPECTORS OF THE THIRD GRADE IN THE TELEGRAPH DEPARTMENT IN INDIA, TO BE HELD IN LONDON IN MAY, 1864.

CANDIDATES must be native British subjects, and not less than eighteen nor more than twenty-four years of age, and must have complied with one or other of the three following conditions:—

1. They must have passed not less than two years in the service of one of the English telegraph companies, or of a foreign telegraphic administration; or,
2. Not less than two years as articled pupils of, or in practice under, a telegraphic engineer; or,
3. Not less than two years in a school or college recognised by the Secretary of State as possessing an efficient class for instruction in chemistry and physics, and during six months of that period must have given special attention to those subjects.

On these points they must be provided with satisfactory certificates, which must be delivered at the department of public works in this office between the 2nd and 18th days of May next, both inclusive, between which days only will applications be received.

The names of the candidates will then be registered, and they will be directed to appear for medical examination before the examining physician, who will attend at this office for the purpose on Saturday, the 21st of May, between the hours of one and three p.m. If then certified to be of constitutions sufficiently vigorous to bear the fatigue and exposure to which they would be liable when serving in India, they will be required to attend, at nine a.m. precisely, on the succeeding Monday and following days at a competitive examination which will be held in this office.

The candidates will first be required to write English from dictation, and, unless found able to do so with accuracy and facility, will not be permitted to remain during the subsequent examination. The other subjects of examination, and the maximum number of marks obtainable for proficiency in each class of subjects, will be the following:—

	Marks.
1. Arithmetic, book-keeping by single and double entry, mensuration	1,000
2. "Euclid:" 1st, 2nd, and 3rd books; and algebra, including simple and quadratic equations	1,000
3. Geography, plane trigonometry, including practical knowledge of methods for heights and distances, use of the logarithmic and trigonometrical tables	1,000
4. Elements of physics, including electricity and elements of chemistry	2,000

No candidate will be passed who shall not obtain 2,000 marks, of which not less than 1,000 must be awarded for physics and chemistry. The candidates who may obtain the prescribed minimum number of marks will be ranked by the examiners in the order of the numbers they may severally obtain; and of these the twenty-five who may stand highest on the list will be appointed.

The successful candidates must, within a month of their nomination, sign covenants, describing the terms and conditions of their appointment, and must embark for India when required to do so by the Secretary of State in Council, who will provide for the expenses of their passage. Any nominee not embarking when required will forfeit his appointment.

Present Classification of Appointments above the Grade of Signaller.

No. of Officers.	Grade.	Monthly Pay of each Officer.

CORRESPONDENCE.

THE ATLANTIC TELEGRAPH COMPANY.

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—Can you or any of your readers inform me what has become of the above important undertaking? It was stated in the daily papers, some months ago, that the necessary capital had been subscribed, the form of the cable decided upon, the arrangements with the contractors completed, the manufacture of the core commenced, and that an effort would be made to submerge the cable in the Autumn of the present year. I, like many others, who are deeply interested in the progress of submarine telegraphy, have watched with considerable anxiety for some public intimation as to the steps which are being taken towards the realization of the great object in view—the uniting the Old to the New World. The company has certainly the good wishes of millions on both sides of the Atlantic, and who will experience much disappointment if another year is allowed to pass by without an attempt being made to establish telegraphic communication between Valencia and Newfoundland. Yours, &c.,

Liverpool. J. P. LOVELL.

BONELLI'S TYPO-ELECTRIC TELEGRAPH.

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—It was my privilege on Monday evening last to attend the Conversazione at Angel-court, Throgmorton-street, to witness the Bonelli Typo-Electric Telegraph in operation. To say that I was exceedingly interested in the working of this beautiful and elaborate apparatus would be but a feeble expression of the feeling which had possession of not only myself but all present; and, indeed, if this most perfect of all methods of electrical communication were not sufficient to recommend itself and make its way to superiority over all others, sure I am that the gentlemanly courtesy and urbanity of Mr. Cook, the managing director, would make up the deficiency. Happily, however, so exquisite and yet so simple a contrivance carries with it its own indisputable credentials.

But I am not going to write a description of this delicate and effective typo-electric telegraph apparatus—hoping to see this done in your pages by some one more competent; and in order that such description should be comprehended by those of your numerous readers who have not seen the telegraph in operation, I would suggest that it be illustrated by diagrams, for the purpose of showing how and by what means the batteries act—how contact is made and broken at various points—and such other information bearing upon the internal mechanism which produces such unparalleled results. Considering the important end attained these appear to be few and comparatively simple; I apprehend, therefore, that a description given in accordance with this suggestion would be most interesting and within the comprehension of all.

Of course the object of this soirée was to bring the merits of the Bonelli telegraph more prominently before the metropolitan public, preliminary to a further extension of the line southward. This is an object which doubtless a great many people would like to see accomplished; and, indeed, it would be small credit to this metropolis if it failed to appreciate so perfect a system, when its merits have been so significantly acknowledged in the North and on the Continent.

Since, however, publicity is the object, it must necessarily be subjected to

* Herschel.

that ordeal which all claimants for public favour, no matter of what description, have to undergo—discussion on certain points connected therewith, which, unless some light can be thrown upon them, appear to be drawbacks or disadvantages.

To the thoughtful observer present on Monday night there was one consideration which, despite the general excellence of the system, could not fail to obtrude itself as a weak point. Suppose, for instance, the Bonelli Line of Telegraph was established between—say London and Manchester; suppose, further, that an important public meeting were being held at the latter place, and some famous orator was speaking there, upon whose lips the nation had learned to hang, and that a special edition of the *Times* was in process, getting his speech in type, fast as the electric wave flashed the words, warm from the fervid lips of eloquence along the wire,—how could those words be caught up and put into type by the type-layers, which are a necessary part of the staff of the Bonelli system of telegraphy? It seems to me impossible; and, therefore, for cases of this sort—which the Morse instrument is capable of doing with perfect ease, because no preliminaries are necessary, and which add so greatly to the income of existing telegraph companies—the Bonelli telegraph would seem to be inadequate. We know, of course, that the speed of transmission exceeds by far the Morse system, or even that attained by the use of Professor Hughes's instrument. But, then, there is the time it takes to *prepare for transmission* in the laying of the type, which, by passing through the apparatus at the sending station, prints it at the receiving station. By the ordinary telegraph, what with the use of abbreviations and other facilities, a speaker's words are transmitted with the same rapidity as they are uttered, so that we get a celebrated speech, delivered 200 miles away, wet from the press, almost before the thunders of applause have died away; or, at all events, before the enraptured audience have recovered the wonted use of their senses. On the other hand, it is inconceivable that the most expert type-layers should be able to get their characters in order with the same rapidity as an ordinary individual would speak. I shall be glad to know how this difficulty is got over, or whether we are to esteem the Bonelli Typo-Electric Telegraph as suitable only for the transmission of ordinary messages, in which there is always a sufficiency of time for setting up the type.

There are other points I should liked to have touched on, but I have already trespassed too far upon your space. The necessity of having five wires must be deemed not quite a favourable characteristic. I have an impression, however, that one wire might be made to answer the purpose.

J. P.

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—Being absent repairing one of the North Sea cables, I was only made acquainted, on my arrival here for shelter, through the kindness of one of our staff, of the invention of the pneumatic arrangement for discharing, &c., long submarine lines being attributed to Mr. Andrews.

Whilst employed in the engineering department I furnished a plan for the short circuiting apparatus at present used by the Submarine Telegraph Company on their Hanoverian and Danish cables, and Mr. Andrews, being engineer at the time, had the instrument manufactured.

Not the slightest alteration was ever made to my original suggestion.

Mr. Andrews' systems were far different from that explained at page 7 in the first number of your journal.

I am, sir, your obedient servant,

JAMES R. FRANCE,

Acting Engineer, Submarine Telegraph Company.

Off Yarmouth, January 12, 1864.

TELEGRAPHIC NEWS.

INTELLIGENCE has been received at the India Board of the safe arrival at Bombay of Lieutenant-Colonel Stewart, R.E., Sir Charles Bright, and staff of engineers, electricians, &c.

TELEGRAPHY IN NEW SOUTH WALES.—Although hardly five years had elapsed since the first introduction of telegraphy into the above colony there were, at the end of 1862, 2,174 miles of line and 2,539 miles of wire. The extension proposed for 1863 consisted of 120 miles of line, the average cost of construction being estimated at £40 10s. per mile.

ONE of the workmen, named Edward Hoy, in the employment of the Electric and International Telegraph Company, met with a dreadful and fatal accident while occupied in repairing the line wire near to the Corporation Bath, Chester. It appears that he was standing by one of the poles when the train to Chester came up and knocked him down, the engine passing over his head and killing him on the spot. We believe that accidents are of frequent occurrence along our telegraph lines from fall or the sudden fracture of the wire under great tension, &c., and also in some of the large factories, or on board vessels in submerging cables, &c.; but we believe that there exists no provident fund for the benefit of those who may meet with injury, or the families of those who may meet with fatal accidents, as in the case of men, &c., employed on our railways.

A LECTURE was delivered on the 6th inst., before the Philosophical Society, Ryde, by T. Webster, Esq., on "Recent Improvements in Telegraphy by Land and Water," illustrated by instruments, specimens of cables for ocean telegraphs, and diagrams. W. H. Anderson, Esq., the president of the Society, occupied the chair, and briefly introduced Mr. Webster to the meeting, and at the close warmly thanked him for the instructive and interesting facts he had laid before them; and all present heartily joined in their president's thanks for the really scientific and practical way in which he had treated the subject.

THE town and fort of Guadur was completely destroyed by fire on the night of the 23rd ult. Great distress in consequence. Guadur is due west from Kurrachee about 400 miles, the place at which the end line of telegraph from Kurrachee, intended to form part of what will be known as the Persian Gulf Line of Telegraph to England, terminates. The telegraph from Kurrachee to Guadur was completed in April last, under the superintendence of Mr. Walton.

PRESENTATION OF A TESTIMONIAL TO MR. W. H. PREECE, C.E.—On the 4th instant the various members of the staff of the south-western district of the Electric and International Telegraph Company, together with those of the telegraph department of the London and South-Western Railway Company, presented to Mr. W. H. Preece, their superintendent and engineer, a most gratifying testimonial of their regard and esteem, in the shape of a handsome gold chronometer watch, and an address on vellum beautifully executed by Mr. W. C. Clarke, of Southampton, to which is appended the names of the subscribers, about 150 in number. The presentation, which was made on Monday, was necessarily of a private nature, it being impossible for the subscribers to leave their respective duties to assemble in an aggregate gathering. The following is a copy of the address:—"To William Henry Preece, Esq. We, the following members of your staff, desire to present you with a testimonial of the esteem and deep regard entertained by us towards you as our superintendent. The marked progress of the district since it has been under your control—the hearty assistance, the able advice, you are ever ready to afford those under your charge—the unvaried kindness we have ever met with at your hands, have been to us a constant source alike of unqualified admiration and unbounded gratitude. Proud to possess as our guide and counsellor one who has on more occasions than once earned for himself the applause and the high reward of the Council of Civil Engineers, our earnest desire is that you may long remain amongst us, to watch over the interests of our employers no less than our own, to steer us on our onward course, our friend, our adviser; and that your life may be enriched with the greatest blessings a great and beneficent Providence has in its power to bestow. With these sentiments in our breasts we beg your kind acceptance of the accompanying watch." The watch bears the following inscription:—"Presented to William Henry Preece, Esq., by the various members of his staff, as a token of the high esteem and regard entertained by them for him as their superintendent. Southampton, December, 1863." Mr. Preece has acknowledged this very pleasing compliment in the subjoined letter to Mr. W. Langdon, who forwarded to him the address and watch on behalf of the subscribers:—"Southampton, January 5th, 1863. Dear Sir,—I beg to return to you personally, and to the members of my staff generally, my sincerest and deepest thanks for the very handsome testimonial which you have presented to me. I do not know that anything could have been done by those with whom I have been so long associated which could have afforded me greater pleasure. I can never contemplate this splendid watch, nor read this eloquent address, without feeling that, however much I may have failed in doing my duty, I have at least gained your regard and esteem. This of itself is a proud satisfaction, without which the gratifying present that accompanies the kind expression of your approval of my conduct as your superintendent would be valueless. I hope I shall continue to merit your goodwill, I will at least endeavour to deserve it. And I trust that we may be long spared to carry on the duties, which have hitherto been so amicably and happily conducted, with the same confidence, the same satisfaction, and the same success. I am, yours very faithfully, W. H. PREECE." Our readers are aware that Mr. Preece is a man of considerable scientific attainments. Two papers written by him and read at the Institution of Civil Engineers, London, of which he is a member, have earned for him—the one on "Submarine Cables," the Telford gold medal, and the other, on "Railway Telegraphs," the Telford premium, being an award of books valued at £30. These papers have both been printed by the institution, and afford much valuable information on the respective subjects of which they treat. The last-named is a work of especial interest, not only to railway managers, but to the travelling public at large. Pointing out the various systems in force on different railways, the author enters into a clear and impartial discussion of their relative merits and disadvantages, with the laudable view of introducing and maintaining such systems only as shall tend, as far as it is possible, to procure security for life and regularity in the traffic. Mr. Preece's contributions to the scientific journals of the day have been by no means scanty. As an electrician he has introduced many improvements in telegraphy, and his system of railway signalling is the most perfect and simple of the day. On many occasions Mr. Preece has rendered good service to the Polytechnic Institution of Southampton and kindred associations in the neighbourhood, and we are glad to have this opportunity of recording the high esteem in which he is held by those with whom he is so closely and intimately connected in business relations.

TELEGRAMS for India will for the future be transmitted from the chief office of the Submarine Telegraph Company, Threadneedle-street, to Marseilles direct, instead of to Paris as heretofore. This will make considerable difference in the time occupied in the transmission of Indian intelligence.

BOARD OF TRADE, WHITEHALL, JAN. 7.—The Right Hon. the Lords of the Committee of Privy Council for Trade and Plantations have received, through the Secretary of State for Foreign Affairs, a copy of a despatch from Her Majesty's Chargé d'Affaires at Constantinople, enclosing a copy of a notice communicated to him by the Director-General of Turkish Telegraphs, to the following effect :—"The Imperial Administration of the Ottoman Telegraph gives notice to masters of vessels that a submarine telegraph cable has been laid in the Straits of the Dardanelles, between forts Bokhalé (coast of Europe) and Negaras (coast of Asia). It is forbidden for any vessel to anchor in the vicinity of the cable, under penalty of all loss or damage resulting thereby."

THE OTRANTE AND AVELONA SUBMARINE CABLE.—In a former number we briefly referred to the completion and shipment of the above cable on board the *Semaphore*. The vessel left Mr. Henley's, the contractor's works at North Woolwich, on the 7th instant. The cable is 62 miles (statute) in length, 43½ miles of which is to be submerged in deep, and 18½ miles in shallow water. Six miles of the shore end are covered with Messrs. Bright & Clark's compound. The conductor was covered by the Gutta Percha Company, of Wharf-road, City-road, E.C., with three coatings of gutta percha and Chatterton's compound to No. 0, then served with towed hemp, and finally with a sheathing of galvanized iron wire. The insulation of this cable is considered superior to any hitherto manufactured, which affords satisfactory proof that great improvements are taking place in the preparation and application of insulating materials, and which must tend greatly to the advancement and progress of submarine telegraphy.

THE MAGNETIC TELEGRAPH COMPANY'S ANNUAL DINNER.—On the 6th inst. the gentlemen connected with the above company entertained themselves at the Canton Hotel, Temple-court, Liverpool, to a capital entertainment, comprising the essentials of an Englishman's life. It has been customary to hold in years previous to the present an annual tea party; but, whether a change of diet was required or not, the present year was not inaugurated with a tea party. The company mustered in good force, and the table was presided over by Mr. E. B. Bright, the vice falling to Mr. J. Leyland. The President, after proposing the usual loyal toasts, tendered "Success to the Magnetic Telegraph Company." In so doing, Mr. Bright pointed out the experience of many years; and stated that, in 1852, when the company was first formed, the number of stations established by the company was four or five, which, of course, embraced but a small degree of the existing position of the company. At the present time the wires of the company embraced 17,000 miles, and these miles were junctionised at different points by 500 stations. This epitome, of course, is conclusive evidence as to the good management and perspectiveness of the company; and when it is added that, within a few months, the wires of the company will extend directly from Liverpool to India, it is unnecessary to add a good and grateful compliment to those who direct the management of the Magnetic Telegraph Company. There were numerous toasts proposed and responded to. Mr. J. L. Walsh, in happy and appropriate terms, proposed "the Health of the Chairman," which was responded to in a speech which elicited from those present expressions of good hope that in future years the Magnetic Company would still inaugurate the commencement of each year by an assemblage which embraced all good and kindly feeling, and which tended and at the same time made those connected with the Magnetic Telegraph Company more happy, more genial, and more fruitful in their labours to the company and themselves.

MISCELLANEA.

THE duties of a clerk of the telegraph would be extremely simple, requiring only accuracy and attention in noting down and transmitting notices, with a certain degree of expertness, easily attained, in working the instrument. These qualifications are frequently possessed, in a remarkable degree, by a very deserving class of persons, to whom our state of society has hitherto assigned no congenial occupation. The deaf and dumb might, in the telegraphic department, find employment peculiarly suited to their education and powers. Accustomed from their infancy to abbreviate as far as possible, by signs, their symbolic language, they would quickly attain a degree of conciseness in spelling, which, in addition to the omission of the smaller words, would enable them to transmit, with astonishing rapidity, a lengthened despatch; whilst a habit of attention enforced by their infirmities would be favourable to the accurate performance of their duties. The idea of uniting a great political and mercantile enterprise with a charitable object may excite a smile, but cannot diminish the value of the undertaking in the eyes of those whose support the writer is most anxious to secure. It may be observed that a method as effectual as the alarum for those who can hear may be employed in connexion with this instrument to awaken the deaf from the soundest sleep.—*W. F. Cooke's Pamphlet in* 1836.

CANDIDATES for the vocation of telegraph clerks should be capable of writing a free and distinct hand, of spelling correctly, and, as correspondence will form a portion of their duties, of adapting their communications to grammatical formula; a slight acquaintance with arithmetic is also essential; higher attainments than these are not actually indispensable to the ordinary clerk, although they may realize to their possessor advantages which the less accomplished would scarcely have reason to expect or hope for. An "instrument clerk" may be quite competent to telegraph or receive a despatch in a foreign language, and yet not understand a single word of it; but, as the Continent and many other parts of the globe are intersected by the telegraph, clerks and other officials must of necessity be located in foreign countries, and to those who are privileged with such stations the qualifications of a linguist will form an important element in moulding the eventualities of their career. That foreign situations are generally more lucrative than appointments in this country is an admitted fact, and when they are at disposal it is obvious to whom the preference would be accorded, unless favouritism or interest interpose; besides there are foreign departments, attached to which are numerous *employés*, in the chief home offices of the British telegraph companies, to which clerks who are conversant with the language of other countries may be drafted. Although allusion has been made to the favourable circumstances under which the accomplished scholar identifies himself with the service of those companies that have direct communication with other nations, it must not be construed that the official who is destitute of such acquirements should consider his position to be stationary, as, on the contrary, his course may be a progressive one. Constant practice enables him to signal—*i.e.*, to send and receive messages and to write with celerity; and if he applies himself to his duties as assiduously as is expected of him, and determines upon becoming acquainted with the why and the wherefore, he may not only render himself a proficient instrument clerk, correspondent, and accountant, but also attain to a thorough knowledge of the principles of electricity, which operates so surprisingly and with such exquisite accuracy in exchanging thoughts, although conceived in different climes and hundreds of miles apart, with the rapidity of lightning, hence annihilating distance and concentrating time, conveying tidings of the movements of an army, the rise and fall of dynasties, or the desires of a peasant, with like facility and marvellous speed. If the acquisition of a knowledge of the mysteries of this wonderful agent be the clerk's ambition and aim, opportunity will aid the will in demonstration of the fact that the zenith of his aspirations is within his flight, and perhaps assist in distinguishing him as an illustration of the truthfulness of the poet's sentiments—

> "There is a tide in the affairs of men,
> Which, taken at the flood, leads on to fortune."

In the telegraph management there is a feature that is especially commendable. We allude to the solicitude for the development of the mental faculties, as evinced by the establishment of a free library of good, useful, and entertaining works, treating on all subjects, which are at the disposal of the clerk, who has generally an abundance of time to devote to the mind's culture; the means, therefore, of enriching himself in knowledge are within his reach—a literary repast is spread, and he is invited to partake of it. The various grades in the correspondence, and the higher positions in the engineering department, shines forth in the prospective as stimulants to exertion—as rewards to diligence, perseverance, and adherence to the regulations laid down for his guidance. The juvenility of many of the clerks denotes a freshness to business—a recent withdrawal from school to take part in the active concerns of life. Youths of fourteen are deemed eligible for the post, and sharp intelligent lads sometimes enter the service even at an earlier age, and the employment seems so congenial to their taste, that, unlike other tasks, it is viewed by them with the pleasurable emotion of an agreeable pastime; nor does this feeling abate—it grows with their age, and, as a consequence, they frequently out-distance those whose induction dates at a later period of life, and hence earn for themselves the reputation of first-class readers.—*Bond's Handbook of the Telegraph.*

ENERGY.—The cultivation of this quality is of the greatest importance; resolute determination in the pursuit of worthy objects being the foundation of all true greatness of character. Energy enables a man to force his way through irksome drudgery and dry details, and carries him onward and upward in every station in life. It accomplishes more than genius, with not one-half the disappointment and peril. It is not eminent talent that is required to ensure success in any pursuit, so much as purpose,—not merely the power to achieve, but the will to labour energetically and perseveringly. Hence energy of will may be defined to be the very central power of chaacter in a man—in a word, it is the Man himself. It gives impulse to his every action, and soul to every effort. True hope is based on it,—and it is hope that gives the real perfume to life. There is a fine heraldic motto on a broken helmet in Battle Abbey, "L'espoir est ma force," which might be the motto of every man's life. "Woe unto him that is faint-hearted," says the son of Sirach. There is, indeed, no blessing equal to the possession of a stout heart. Even if a man fail in his efforts, it will be a great satisfaction to him to enjoy the consciousness of having done his best. In humble life nothing can be more cheering and beautiful than to see a man combating suffering by patience, triumphing in his integrity, and who, when his feet are bleeding and his limbs failing him, still walks upon his courage.

AN instrument, called the "Bathorèomètre," has been invented by Messrs. Ludwig & Kromeyer, of New York, on the principle of closing the electric circuit by means of a substance interposed between the electrodes, by which thicknesses of substances, such as hair, spiders' web, &c., may be determined with exactness to the twelve-millionth part of an inch.

THE inventive genius of swindlers seems to keep pace with the improved means brought to bear for effecting their apprehension or in defeating their schemes upon the purses of the credulous. A good illustration of the fertility of invention displayed by those rogues who live upon their wits was furnished in Liverpool lately. It appears that a respectably-attired young man went to the house of Mrs. Stower, No. 4, Bedford-street North, and stated that he was a telegraph clerk, that a telegram had just arrived from a "foreign country," and which could only be delivered to Mrs. Stower or her husband. The "clerk" told Mrs. Stower that if she sent her son down with him to the house of Mr. Roberts, the Secretary to the Electric Telegraph Company, who resided in Hope-street, he would send the message to her. Mrs. Stower sent her son with the man as he desired; but on the way to Hope-street the fellow told the lad that he must return and bring with him 7s. 5d., or he could not have the telegram. The lad returned as desired, brought the money, which he handed to the man, who gave him in exchange an envelope, which he said contained the "message." The lad returned home and gave the envelope to his mother, who, when she opened it, found that, instead of containing the expected telegram, the only thing inside was a blank sheet of paper. Mrs. Stower went to the detective-office and informed the police as to what had taken place. On leaving the office and proceeding along Whitechapel she met the person she so much desired to have an interview with—"the telegraph clerk" who had called upon her in the morning. Mrs. Stower at once gave the fellow into custody, and on being taken to the police-office he gave the name of James Taylor, and said that he was a surgical instrument maker. Mrs. Stower is not the only person whom he has victimised, for other complaints have been made at the detective-office by parties who have paid for Taylor's "messages."

SINGULAR MODE OF CAPTURING GYMNOTI.—The marshy waters of Bera and Rastro are filled with innumerable electric eels, who can at pleasure discharge from every part of their slimy yellow-speckled bodies a deadening shock. This species of gymnotus is about six feet in length. It is powerful enough to kill the largest animals when it discharges its nervous organs at one shock in a favourable direction. It was once found necessary to change the line of road from Uritneer across the Steppe, owing to the number of horses which, in fording a certain rivulet, annually fell a sacrifice to these gymnoti, which had accumulated there in great numbers. All other species of fish shun the vicinity of these formidable creatures. Even the angler, when fishing from the high bank, is in dread lest an electric shock should be conveyed to him along the moistened line. Thus, in these regions, the electric fire breaks forth from the lowest depths of the waters. The mode of capturing the gymnotus affords a picturesque spectacle. A number of mules and horses are driven into a swamp, which is closely surrounded by Indians, until the unusual noise excites the daring fish to venture on an attack. Serpent-like they are seen swimming along the surface of the water, striving cunningly to glide under the bellies of the horses. By the force of their invisible blows numbers of the poor animals are suddenly prostrated: others snorting and panting, their manes erect, their eyes wildly flashing with terror, rush madly from the raging storm; but the Indians, armed with long bamboo staves, drive them back in the midst of the pool. By degrees the fury of this unequal contest begins to slacken. Like clouds that have discharged their electricity, the wearied eels disperse. They require long rest and nourishing food to repair the galvanic force which they have so lavishly expended. Their shocks gradually become weaker and weaker. Terrified by the noise of the trampling horses, they timidly approach the brink of the morass, where they are wounded by harpoons, and drawn on shore by non-conducting poles of dry wood. Such is the remarkable contest between horses and fish. That which constitutes the living but invisible weapon of these inhabitants of the water—that which, awakened by the contact of moist and dissimilar particles, circulates through all the organs of animals and plants—that which, flashing amid the roar of thunder, illuminates the wide canopy of heaven—which binds iron to iron, and directs the silent recurring course of the magnetic needle—all, like the varied hues of the refracted ray of light, flow from one common source, and all blend together into one eternal all-pervading power.—*Baron Von Humboldt.*

TO CORRESPONDENTS.

As information respecting Improvements, Extension of Lines, and Progress of New Undertakings will at all times be most acceptable, we hope that our readers will kindly render us assistance in our efforts to establish a Journal worthy in all respects of the great interest it seeks to represent, by furnishing us with brief notices of events and occurrences in connection with Telegraphy.

Several inquiries having been addressed to us respecting the India telegraphic appointments, we have inserted in another portion of the journal the instructions issued by the India Board.

It is our intention to publish in our columns a historical account of the late extensive experiments carried on under the direction of the Telegraph Committee of the Board of Trade, together with the result of numerous investigations which are not included in the "Blue Book."

The review of Mr. Culley's new work, and the continuation of our article on Telegraph Property, are unavoidably postponed until next week.

Communications intended for publication must be authenticated by the names and addresses of the writers; not neccessarily for insertion.

Letters relating to Advertisements are to be addressed to the Publishers. All other letters and communications to be addressed to the Editor of the *Telegraphic Journal*, 5, Suffolk-lane, Cannon-street, London, E.C.

The *Telegraphic Journal* can be had of Messrs. SMITH & Co., Strand; Messrs. DAWSON & Co., Cannon-street West; Messrs. KENT & Co., Paternoster-row, London. Messrs. HEYWOOD & Co., Manchester; at the various railway stations; and of all news-agents, &c., &c.; or it can be supplied, if preferred, direct from the Office on the following terms (paid in advance):—

	s.	*d.*
Quarterly	4	4
Half-yearly	8	8
Yearly	17	4

TO ADVERTISERS.

The *Telegraphic Journal* is the most effective medium for inventors, patentees, contractors, manufacturers of insulating materials and electrical apparatus to submit their various specialities to the consideration of secretaries and managers of telegraph or railway companies, and other persons engaged in electrical and telegraphic pursuits.

Clerks, assistants, manipulators, and instrument makers, seeking employment, &c., will find the *Telegraphic Journal* a ready means of making known their requirements.

Advertisements must be delivered to ensure insertion before SEVEN O'CLOCK on Thursday evening in each week. The charges for Advertisements are—

	£.	*s.*	*d.*
Whole page	4	4	0
Half ditto	2	10	0
Quarter ditto.	1	7	6
Four lines and under (single column)	0	3	0

Single Advertisements from the country must be accompanied with stamps in payment.

THE MALTA AND ALEXANDRIA CABLE.

WE are sorry to have to announce that the above important line of Submarine Telegraphy has again ceased to act, and more so as we are informed that, had there been a ship furnished with the proper appliances for raising and repairing the cable, the interruption would have soon been removed. It is believed that the injury has been caused by the severance of the cable by an anchor, and in a locality where no difficulty presented itself to effect a speedy restoration of the communication, had there been, as we have already observed, a ship available.

With the princely revenue which this line yields, it is much to be regretted that no ship is kept ready on the spot, to repair such injuries as might occur. We believe that the lessees have made every effort to perform their obligations to the Government and the public. They certainly did not bargain to keep a vessel always in readiness. The Government, on its part, has failed in its duties. It is well known that there were vessels at Malta, on other occasions, which the lessees could have easily fitted up with the necessary apparatus for raising and repairing the cable, but the loan of such vessels was refused. The lessees were compelled, as they are now compelled, to resort to our ports at home, for a vessel for the purpose. The stoppage and the delay which must, of necessity, take place before the communication is renewed, are of serious consequence to the public and our telegraph companies, more especially to the Submarine Telegraph Company, who, in order to meet the public requirements incurred considerable expense in providing instruments, manipulators, &c. We believe that, since the interruption has taken place, the loss to this company alone is upwards of 120 messages per day; but the loss to the public is still greater, and the more annoying, because it must extend over as many days as it ought to have been hours.

Notwithstanding these mishaps, we are exceedingly glad to be in a position to assure the friends of submarine telegraphy, and the public generally, that the line between Malta and Alexandria is in an excellent state of preservation, exhibiting no signs whatever of deterioration in its electrical condition. The messages are now transmitted per telegraph to Malta, where they are posted and conveyed from that station to Alexandria. As Parliament soon meets, we hope that the non-fulfilment of the terms of the lease, on the part of the parties concerned, will be brought before it, and that the matter will be thoroughly sifted. The following are the clauses to which we have referred:—"In case at any time during the continuance of this lease it shall be necessary to take up any part of the cable, which cannot be taken up by the use of small boats, for the purpose of repairing the same, the same shall be taken up and repaired, or replaced, by the lessees, and the expenses borne and paid in manner following, viz.:—'If any Government vessel, suitable for the purpose, shall be then at Malta, and shall not be required for other purposes (of which the Government shall be the sole judge), the Government shall, or if any other Government vessel suitable for the purpose can be furnished, the Government may, if they so think fit, lend such vessel to the lessees, for the purposes aforesaid, providing such vessel with officers and crew, and defraying all such expenses as shall be required for, or incurred in and about the navigation of the said vessel, other than the expense of coals and fuel, which shall be at the joint expense of the Government and the lessees, but all necessary fittings, to adapt such vessel for the purpose of raising and re-placing the said cable, shall be placed in such vessel, and shall be afterwards removed and the said vessel restored to her original state and condition, by and at the expense of the lessees; and all machinery, apparatus, and instruments, which shall be necessary for the purpose of raising, repairing, and laying the said cable; and the engineers, electricians, and cablemen, shall be provided, maintained, and paid, by and at the expense of the lessees. If no such vessel shall be furnished by the Government, the lessees shall provide a suitable vessel, and shall provide officers and crew for the same, the hire of which vessel, and the hire and maintenance of the captain and crew, and all such other expenses as shall be required for, or incurred in or about the navigation of the said vessel, and also the insurance of the said vessel, shall be at the joint expense of the Government and lessees, but all other matters shall be provided and done, and all expenses borne in the same manner as if such vessel had been a Government vessel, and lent to the lessees for the purpose aforesaid.'"

THE FIRE BRIGADE TELEGRAPH.

CAPTAIN SHAW, the Superintendent of the London Fire Brigade, has recently issued his Annual Report for the year 1863.

It contains a general statement of the working of the Brigade, with interesting returns, showing the number, cause, locality, and other particulars of the various fires that occurred in London and the suburbs during the year. The following extracts may prove interesting to many of our readers:—

"During the past year the telegraph has been extended from the foremen's stations to those in their respective districts, thus completing the communication throughout the establishment, from the chief station, in which I reside, to those most remote—in Ratcliff, Baker-street, Westminster, and Rotherhithe respectively. The system which I have adopted is of the simplest possible kind, as will be seen by reference to the accompanying map. Every line is complete in itself, with a dial or alphabetical instrument at each end; thus, a stoppage or break in any one line does not interfere with the general communication, as would be the case if several stations were on one circuit. From Watling-street I ordinarily communicate only with the foremen, and through them with the stations in their respective districts; but, by a simple contrivance, I can at any moment be placed in direct communication with any station, thus avoiding the delay caused by repeated messages at an intermediate point. I have adopted this mode not only to be able to collect the necessary force of men and engines at any given spot, in the shortest possible time, according to my requirements at the moment, but also for the purpose of avoiding the errors inseparable from a system of mere alarms, as used in America, by which the whole force of a fire brigade is liable to be constantly turned out for matters of very little consequence, it being an invariable rule that the importance of every fire is greatly exaggerated by momentary panic in the vicinity. The saving thus effected in the time and labour of the men, as compared with the old system of running with 'calls and stops' from station to station, is in itself a great addition to the available strength of the establishment, and that at the very time when the services of skilled firemen are most needed, while the

advantage of rapidly transmitting the calls, and thus ensuring the early arrival of men and engines at fires, is incalculable; besides which I am now enabled to issue orders and conduct almost the whole of the duties of the establishment by this means in a much quicker and more satisfactory manner than formerly."

It may also be stated that, taken in a pecuniary point of view, the addition of the Telegraph to the Fire Brigade System has proved most satisfactory. The amounts hitherto paid for "calls," whether for actual fires or false alarms, have formed a large item of expenditure in the management, as, in addition to the fees paid, the expense of sending out the engines must be taken into consideration.

At some of the stations this service is done by contract, *i.e.*, the necessary number of horses is provided by the contractor, and a charge made each time they are sent out.

An elaborate diagram accompanies the Report, showing the connections of the various stations as explained in the foregoing extract.

The wires and instruments have been provided by the London District Telegraph Company, the latter being made by Messrs. Siemens & Halske. The magneto-alphabetical instruments have been adopted; and, from their extreme simplicity and durability, they are well suited for this service.

We understand that the Dublin Fire Brigade are also having a Telegraph provided for their service, as well as several other large towns in the north of England.

AMENITIES.

Probably some of our readers will not have forgotten the sentiments that were dropping from the lips of the good and eloquent Judge Talfourd, when the icy messenger summoned him without warning from the head of an earthly tribunal—from the judicial bench to which he had been but recently elevated to grace and adorn, and while even the ermine which he honoured sat new upon him—to a higher tribunal, before which may we all be as well fitted to appear. He was deploring the grievous effects of class exclusiveness, and dwelling upon the probable decrease of those painful cases which wound the susceptibilities of the tender-hearted judge, who in the worst of cases cannot but sympathise with the fallen, and speculate reflectively how different things might have been had the circumstances been other than they were, and how often (too often, alas!) those circumstances—made by others, unnecessarily—prove gratuitous fabrications not to be laid at the door of Providence, as men so often find it convenient to do, while the wretch who suffered was not unfrequently the victim of those very man-made circumstances, with perhaps neither the power nor the will to control them.

These eminently humane sentiments met with a response in the breast of every right-minded man and woman throughout the land, especially when they were taken in connection with the awful circumstances of their being spoken on the confines of the unseen world, for it was like a voice from the land of spirits. These words, perhaps, were not spoken in vain. The impenetrable barriers of ice which erst had separated class from class had been thawed by real sympathy to no inconsiderable extent. Nevertheless it makes one shudder when facts come to light at times which reveal that there are myriads existing in a mysterious isolation, as much cut off from the sympathy of the rest of the world as the natives of Patagonia, or the extinct Artures of the Orinoco. Speaking of the nation as a whole, the social fabric is not inaptly compared to an edifice which a skilful builder has put together. The "upper ten thousand" form the dome, and royalty is its apex. Trace the building throughout its fair proportions down to the foundations. What does so noble a temple rest upon? Surely it should be founded on a rock. The lower tiers, basement, and foundation of this towering edifice, whose summit glitters in the empyrean, are formed by the labouring and artizan class. How are they cemented to the layers above? It were hardly wise they should be as lose disjointed fragments of brick, lath, and plaster.

There is, however, a class exclusiveness on a less important scale than this, and, indeed, where one would think it was the interest, at least of the more fortunate part, to render its existence as indistinct and innocuous as possible. Generally speaking no sympathy can be said to exist between employer and employed. The former—having capital to offer in return for the skill and labour of the million, whose only capital is brains and sinew—too often look upon the connection as an ordinary affair of barter, and each party is as much a stranger to the other until the contract is renewed as it is possible for two distinct races to be. This is a general view of the subject, and by no means an agreeable one, taken in connection with the structural fancy above indulged in.

Inter alia, we have been led to make these remarks from the numerous letters which have appeared from clerks and other employés of the different Telegraph Companies, complaining of the unjust aspersions cast upon them from their alleged inferiority in intelligence, and their meagre attainments in electric and telegraphic science, as compared with the same class of persons on the Continent. Such comparison is, to say the least, invidious; nor has it any foundation in fact, so far as we are able to judge. Doubtless there are continental clerks and workmen too, that could put to the blush many holding far higher situations in this country; they are not a type of the class, however, but rare exceptions only, no more indigenous to one country than another. We are personally acquainted with more than one or two individuals, our own countrymen, occupying but very humble stations, who have far sounder and more matured views on electrical and telegraphic points, theoretical and practical, than many eminent men who are nevertheless justly esteemed authorities in their profession: indeed, we are free to admit that ourselves have sat at the feet of these lowly individuals and been all the wiser for it. Gentle souls! they are too modest, and think too lightly of their acquirements ever to become men of note; but an apt man will borrow their brains, or the results thereof, and will become eminent, perhaps rich, by virtue of the possession.

Besides these rare exceptions, however, there is a large number of our telegraph clerks who are really men of superior attainments to the common run of clerks, and are quite posted up in all the generalities appertaining to matters electric and telegraphic; and that there are not more such is, perhaps, as much owing to themselves as the companies' officers they serve under. So much by way of vindication.

We confess we should like to see a greater degree of interest taken in the welfare of so large and important a class as the telegraph clerks and employés; certainly a great deal has been done of late, and there is no better lesson to inculcate than that of self-help; but it is hardly in this direction that our remarks are intended. We are desirous of seeing that spirit of amity pervading the whole mass, from the Board of Directors down to the meanest messenger boy, which alone is capable of cementing them into a body fitly represented by a super-structure, compact and harmonious in its graceful gradations.

No one, we think, can charge any of our large Telegraph Companies with parsimoniousness in respect to the recompense of those they employ, but too often those in authority are apt to overlook the fact that they owe something more to their servants than mere payment for time and labour. A congenial spirit should be evinced, and a familiarity cultivated which need not degenerate into contempt, so that while the one can look up with respect and esteem, the other may courteously show by general urbanity of demeanour that the social status which

renders one distinct from the other is not allowed to obtrude itself in so objectionable a way as to cause the less fortunate to feel himself humiliated on account of his social position. Surely the application of the greatest agent in nature to the requirements of mankind, and the well-being and advancement of the world at large, ought to afford common ground whereon the humblest aspirant after scientific truth and progress should feel himself on a level with a peer of the realm engaged in the same pursuit.

As one means to this end, Directors of Telegraph Companies cannot assuredly do better than contribute by all possible means to render their clerks efficient for the performance of their duties. It is their interest to do so, and surely that is the lowest motive that can be urged.

The establishment of circulating libraries for the use of the employés, embracing every known work of merit on electrical, telegraphic, and kindred sciences, would do much to bring the ordinary working staff into a state of most satisfactory efficiency; nor would it be waste of the companies' funds to distribute gratuitously the current periodical literature of telegraphy among those of their servants to whom a few pence per week is a tax they can ill afford to subject themselves to. It would keep them wide awake to what is going on; they would become interested in matters which probably they never hear of now; and the zest thus created for general as well as specific telegraphic information would bring out latent talent, and in the main repay the outlay tenfold.

Such a company's business would be certain to be done well and efficiently; there would be a stimulus to exertion, and most of all, it would foster the growth of that bond of brotherhood which we conceive to be the nearest approach to a perfect state of society. We shall take an early opportunity of addressing a few words to telegraph clerks, &c., especially.

M. S. B.

MR. R. S. CULLEY'S NEW WORK.*

(*Continued from p.* 16.)

NOTHING is more important to the telegraphist than a thorough knowledge of the laws of resistance, and their application to the testing of lines for efficiency, and for the existence of faults. All principal circuits should be regularly tested daily. These tests should be so recorded, as to be capable of being reduced into units of resistance. The unit of resistance adopted in England, is a single mile of No. 16 copper wire. Such tests will show leakages, and faulty connections, and frequently enable their removal to be effected before they have succeeded in preventing the efficient working of the circuit. Mr. Culley describes the system adopted in France, as described by M. Blavier, but the plan used in England by which these tests are made with differential galvanometers and resistance coils, is far more exact and simple. It is quite possible to reduce the readings of a galvanometer to units of resistance, with much exactitude, but it is far preferable to take these facts direct by the aid of coils.

Part VII. details the nature and effect of faults, and the various methods adopted in discovering them, and their positions. Very little has ever been published upon this matter before, and, if we except a pamphlet by Mr. C. W. Siemens, F.R.S., and a paper read at the Institute of Civil Engineers by Mr. W. H. Preece, we do not know of any printed matters containing the important information required for this branch of the telegraphic calling.

Mr. Culley gives the following important advice:—

Never test for contact by having the earth put on at the testing stations; this method is liable to great error, and has led to much inconvenience.

If *a very good* earth be put on *beyond* the fault, and very near it, it will cause the contact to disappear almost entirely, because the resistance of this new path will be very much less than that of the other wire.

And if the earth be *imperfect*, and be put on between the original station and the fault (the near side of the fault), the contact will not disappear, especially if the wires be clean, so that the resistance of the points in contact be very little.

The fault may appear less, but unless care is taken that the testing battery be not strong enough to give a "*full deflection*" the variation in the resistance of the circuit may escape notice.

The following is new and useful:—

In a tunnel the place of a fault may be found thus:—Put a current of 40 cells, or more, upon the wire at the mouth of the tunnel, disconnecting the other end. Wrap one bare end of a piece of covered wire with wet cotton waste, and connect the other to a detector in connection with the rail. Run the waste along the wire, carrying the detector forward until the needle is deflected by the current escaping through the waste at the fault. The detector may be fixed to a staff ending in an iron point, which can be set upon the rails, which should be moistened to make good earth. The wire may also be cut and tested in sections.

Indeed, this part is full of interesting matters, and very sage and useful advice. We can only regret that it is not more copious.

The remaining portion of the work is devoted to a description of the various signal apparatus employed in telegraphy:—switches, commutators, keys, turnplates; the printing and needle telegraphs; the construction of a line; and the strain and dip of suspended wires. The latter information is particularly interesting, and should be carefully studied by those who have the charge of those tremendous spans that cross the streets and waterways of our metropolis. The mathematical formula of the law of the question is:—

$$S^2 : s^2 :: D : d.$$

Where S is the original span, s the proposed span, D the original dip, and d the dip required by the increased span, to preserve the same strain and tension. From this formula may be ascertained "not only the dip of any proposed span, but the span of any proposed dip."

A wire should never remain tightened up to more than one-fourth of its breaking strain, which varies with every sample of wire. It should be pulled up first to one-half of the breaking strain to test it, and afterwards slacked out. Where the breaking of the wire would be inconvenient, it may be tested before it is put up.

An appendix is added, containing some very valuable and instructive notes. Those relating to the construction of scales, for tangent and sine galvanometers, are particularly useful.

We cannot too heartily thank Mr. Culley for the very useful addition he has made to our literature, and we only wish that other celebrities in this science would follow his meritorious example. There is nothing gained by unpublished experience. It is far better to throw it widecast over the profession. Telegraphy is a science in its infancy, and it is only by such labours as those of Mr. Culley's that it can ever be brought to maturity. An eminent philosopher once said, that he found as much pleasure in imparting knowledge as he had received in acquiring it, and we can only wish that the same sentiment would occupy the minds of our own electricians. It is because our own telegraph engineers have been so chary in wielding the pen that they are held in such little repute in the scientific world, at home and abroad; whereas, really, if the truth were known, it would be found that we possess in England talent of the deepest kind, and genius of the profoundest nature. Victories, as proud as those of Waterloo or Trafalgar, have been gained in the field of telegraphy, but we have missed the chronicler to immortalise them. We hope Mr. Culley has commenced a new era.

* A Handbook of Practical Telegraphy. By R. S. CULLEY, Telegraphic Engineer and Superintendent. London: Longman, Green, and Longman.

OCEANIC TELEGRAPHY.

I. *The Deep-Sea Bed of the Atlantic and its Inhabitants.*

By Dr. G. C. WALLICH, F.L.S.

[A HIGHLY interesting and instructive Paper, contributed by Dr. G. C. Wallich, a gentleman well known for his deep-sea soundings and investigations, and the valuable services rendered by him to the science of submarine telegraphy, appears in the first number of an excellent publication recently established under the title of "The Quarterly Journal of Science."* Dr. Wallich accompanied the expedition which sailed under the command of Captain McClintock to survey the proposed northern route for an Atlantic

* John Churchill & Sons, New Burlington Street.

Telegraph; and the valuable information which he then obtained, and in a subsequent survey of the bed of the Atlantic, renders the Paper peculiarly interesting at the present moment, when the subject of deep-sea telegraphy engages so much of the attention of the scientific and commercial portion of the community. We also trust that the perusal of the Paper now re-produced in our columns will be the means of inducing many of our readers employed in telegraphic pursuits, as engineers and electricians, to study a subject, a knowledge of which must greatly tend to promote their success in a new but honourable profession.]

The sounding-machine has already conducted us to the confines of an unexplored world. It has enabled us to penetrate the secret so long and so stedfastly concealed by nature beneath the waters of the ocean, by placing within our grasp the still living forms of creatures differing in no material respect from some of those inhabiting moderate depths, yet capable of sustaining existence under the extraordinary conditions known to prevail amidst the more profound abysses of the sea-bed. In short, it has taught us that our preconceived views concerning the incompatibility of these conditions with the performance of functions which are essential to life, are erroneous, and demand most careful revision.

The fact, as thus stated, appears simple enough, and may by many persons be regarded as involving purely scientific issues. It will be our aim, however, to show that this is by no means the case; and that, whilst the interest attaching to the discovery of animal life under such circumstances is undoubtedly great, and likely to lead to valuable results in every department of Natural History, the practical bearing of this discovery on the question of Oceanic Telegraphy is of no less important a character. But in order to render ourselves intelligible, we must briefly direct attention to what was known on the subject prior to the time when it assumed its present aspect through the discovery of living star-fish procured from a depth of nearly a mile and a half below the surface.

Without stopping to notice the various conjectures regarding the nature of the deep-sea bed which had previously been hazarded, it may suffice to mention that specimens of the material of which it is composed were, for the first time, systematically obtained about ten years ago. These consisted, for the most part, of an extremely fine mud, with a large proportion of microscopic shells belonging to one of the simplest forms of animal life with which we are acquainted. Some of the shells retained a considerable portion of the gelatinous substance of which the bodies of this class of organisms is composed. But at this point the evidence failed. For whilst the fact of these organisms having been raised from vast depths was too clearly established to admit of the slightest doubt, it is manifest that they might have been drifted from shallow water by oceanic currents, or have lived near the surface of the sea, and gradually subsided to the bottom after death. Accordingly, the mere presence of the gelatinous substance of which their bodies are formed, when taken in connection with the well-known preservative power of sea-water highly charged with saline matter, affords no proof whatever of the creatures having lived in the localities from which they had been conveyed by the sounding-machine. But although the determination of the question as to whether animal life can be sustained at such depths was reserved for a later period, these earlier soundings were not barren of highly important results; for they enabled Professor Ehrenberg, on comparison of the material obtained from the bottom with that entering into the formation of chalk, to announce the extraordinary fact that this rock is built up, atom by atom, of shells similar to those met with in such profusion along the bed of the ocean; and further, that it must have been deposited under conditions similar to those now prevailing; thereby furnishing the clearest proof that the great forces which were in operation at the sea-bed countless ages ago are in operation still; and will, in all probability, continue to be so through all time.

We now arrive at the period when the survey of the sea-bed received a fresh and powerful impulse from the project of establishing communication between Europe and America by means of a telegraphic cable. With a view to ascertain the general contour and composition of the portion of the Atlantic it was proposed to traverse, an expedition was sent by the Government of the United States to sound from shore to shore. But, unfortunately, the information elicited in the course of this survey was so vitiated by inaccuracies as to have induced the eminent officer, then in charge of the hydrographic department at Washington, to pronounce it untrustworthy. A second expedition was accordingly equipped, under the auspices of the British Government. Of the accuracy of the depths recorded on this occasion there could be no doubt. But the intervals between the positions at which soundings were taken were so great, and the means of obtaining specimens of the bottom so imperfect, that, looking at the matter as we now do after the event, it seems impossible to regard the information elicited as in any degree adequate to meet the requirements of the enterprise for which the survey was undertaken.*

It is true these soundings, as far as they went, indicated no extreme alternations of level along the course traversed. But, on the other hand, nothing could be more hazardous than to assume, because a certain degree of uniformity as to depth manifests itself at the isolated spots on which soundings were taken, that a like degree of uniformity must prevail over the wide intervening spaces. Of the spaces themselves we know literally nothing. Nevertheless, on these imperfect premises was it maintained, and by many persons believed, that the entire central tract of the Atlantic, instead of being characterized by variations of level and occasional areas of naked and perhaps rugged rock, such as we might expect to encounter here and there in a region so extended, consists of a level plateau, the entire surface of which is covered by a soft stratum of mud, similar to that indicated by the earlier soundings. Now, it must be obvious to every one that, however steep a submerged declivity may be, unless the depth is ascertained at two or more consecutive points, the information elicited will be the same as if the sounding-machine had been dropped on the most perfect level. And accordingly, for aught these soundings have shown to the contrary, the bed of the Atlantic may present features the most opposite to those that have been ascribed to it. But let us not be misunderstood. It is neither our intention to assert, nor do we believe, that insuperable alternations of level are likely to be encountered. We simply deprecate the hasty adoption of a view so unsubstantiated by proof, and so calculated, if erroneous, to interfere with the accomplishment of one of the most important enterprises of the day.

It should be borne in mind that the supposed plateau does not comprise a limited area, but one extending for upwards of a thousand miles across the basin of the Atlantic. Now, there is no parallel case to this in any portion of the present dry land. And, since there is no ground for the belief that such a vast area could possibly have remained unaffected by the agencies which produce modifications in the earth's crust elsewhere, it is—to say the least of it—extremely improbable that so signal an exception should occur only along that portion of the sea-bed which has been selected as the site of the telegraphic cable. We say *only*, because, judging from soundings taken elsewhere, it is manifest that alternations of level are the rule rather than the exception, and that, in some cases, they are of an important kind.

But it is not necessary to have recourse to soundings in order to prove the accuracy of this opinion. The islands that rise so abruptly in many portions of the Atlantic, if reduced somewhat in elevation, might occur over and over again within the intervals at which the depths have been recorded, and yet be completely overlooked. Their existence is known simply because they are lofty enough to appear above water. It would be an act of rashness, therefore, to assume that formations similar in their character, but of smaller size, do not occur in positions where they still remain unrecognized.

Of what then, it may be asked, does our knowledge regarding the contour and composition of the sea-bed really consist? The answer to this question is by no means unsatisfactory. Thus, it is certain that in no region of the ocean in which soundings have heretofore been attempted with adequate apparatus is the depth so inordinate as to be beyond reach. It is equally certain that, as a general rule, the depths are moderate—that is to say, rarely exceeding 2,500 fathoms, or a trifle under three miles; that, for the most part, the bottom is composed of a soft but tenacious mud, consisting either of an admixture of organic and inorganic *débris*, or of some of these constituents more or less uncombined with the other; and lastly, and pre-eminently perhaps, that deep-seated currents, if they prevail at all, are exceedingly rare and too feeble to produce the slightest deleterious effect upon a submerged tele-

* To render this statement intelligible, it may be mentioned that along 1,300 miles of the Mid-Atlantic telegraph route, only forty-one soundings were taken, the intervals varying between 32 and 71 geographical miles.

graphic cable. These, we venture to say, are no unsatisfactory results when weighed against the limited and imperfect nature of the opportunities that have hitherto been afforded for the exploration of the sea-bed; and so far from being of a disheartening tendency, they offer conclusive evidence that the perfection of our knowledge with regard to the conditions prevailing along any given tract of the sea-bed, falls readily within our powers, and is merely a question of time and perseverance.

(To be continued.)

THE INTERNATIONAL EXHIBITION, 1862.

(*Continued from p.* 27.)

5. *Practical Applications of Electricity other than Telegraphic.*

The *applications* of electricity to the *industrial arts* are not very numerous or important. No illustrations were shown of the *process* of electro-plating, probably the most important of these applications.

Medical apparatus are exhibited by Bellhouse, Pulvermacher, Moreau, and others. The criticism of these instruments can only properly be made by medical men.

Electric clocks are represented by several good examples of old plans, and by two new plans of considerable merit. In the first of these, designed by Mr. Jones, the clock is regulated from a standard clock by the retardation or acceleration of the pendulum produced by the electro-magnetic action on the pendulum of currents received through a coil on the bob at each beat. By this arrangement a temporary interruption of the electric circuit will produce no sensible error, and even a permanent interruption will not stop the clock. The second plan is exhibited by M. Bréguet, of Paris, and consists of a method of putting the secondary clock or clocks in unison with the controlling or regulating clock once every hour, or every six or twelve hours, instead of every pendulum beat. By this plan, among other advantages, the difficulty of obtaining the required contacts from the standard regulating clock without impairing its time-keeping qualities is avoided.

The magneto-electric light is a novelty of great importance, in which steam power is substituted for the voltaic battery, as the generator of the powerful current required. It is probable that this invention will enable the electric light to be extensively used in lighthouses and elsewhere. The electric loom, engraving machine, target, boiler feed, railway break, and printing press, will be described at length in the body of this report, although exhibited in Classes VII. and VIII. Several of these ingenious inventions have such merit as will probably lead to their very general adoption.

Two causes interfere with the extensive adoption of electricity as a mechanical agent. The force, though easily directed, is but small at best; and ordinary workmen are unable to trace out and to remedy defects which may occur in the circuit. Even an unpractised eye will frequently detect what is wrong in mechanical arrangements, but in electric communications a practised electrician will sometimes be puzzled for a while to distinguish the cause of failure. The public is, therefore, probably right in eschewing the use of electricity whenever the required object can be effected by mechanical means.

6. *Concluding Remarks.*

Up to the present day the chief practical service rendered by the science of electricity is the rapid or instantaneous conveyance of intelligence in some form from place to place.

It is somewhat the fashion now to decry the value of the services thus rendered by the electric telegraph. The merchant by its use hardly increases his gains; the soldier resents the interference of which it is made the agent; and the statesman is harassed by the imperfect information it conveys. Even the public complains of receiving the heads of chapters followed by their contents only when their interest is gone. But this reaction rests on narrow grounds.

We may, for argument's sake, disregard the services rendered to governments and generals. The telegraph is an instrument in their opponents' hands as well as in their own—an instrument which, like all others, will be of most advantage to those who have most skill to use it; we may grant that merchants can obtain little news tending exclusively to their own special profit, and that the establishment of rapid communication may even lessen the gains of some by diminishing risks which cannot be borne without large capital; but after granting all this, we have left untouched the main claim to favour, and we may still say that the electric telegraph renders great services to the public at large in the same sense as railways, steamers, and free trade itself may be said to benefit the world. The telegraph is one great agent in the work of compensation, by which the deficiencies of one country are made good from the surplus products of the others. The means of making known a want widely and rapidly are of equal importance with the channels through which the required supply is transmitted. Probably no benefit of equal value is purchased so cheaply by the public.

It is now time to pass to a more detailed consideration of the objects exhibited, and the writer of this report may here say that no one can feel more strongly than he does that the praise or blame of a "Jury" or an "Expert" are very insignificant matters compared with the ultimate award of the public. His aim has been to give such an account of the construction of each instrument as may enable the object of its inventor and the nature of its performance to be understood, pointing out at the same time the apparent merits and defects of each scheme.

It is hoped that the following account will at least form a record of the construction and performance of electrical instruments thought worthy of exhibition and reward in 1862. The various classes of instruments and apparatus will be described in nearly the same general order as that in which they have been mentioned in this introduction. In order to keep within reasonable compass, it has been thought best in general to avoid mention of instruments which are not exhibited.*

† THE CONSTRUCTION OF TELEGRAPHIC LINES.

1. *Successful Submarine Cables.*

The first practical submarine cable was laid by Messrs. R. S. Newall & Co., in the autumn of 1851, from Dover to Calais, a distance of about twenty-seven miles. Specimens of this cable, which is still at work, are exhibited by the Submarine Telegraph Company (United Kingdom, 2,971), and by Mr. Brett (United Kingdom, 2,863), promoter of the company, who also exhibited a specimen in 1851. This cable is made as follows:—

Four copper conducting wires, No. 16, B.W.G. (0·065 in. diameter), covered separately with gutta-percha to No. 2, B.W.G. (0·284 in. diameter), are twisted together with a tarred hemp covering, and the rope thus formed is again served with tarred hemp. This core is covered by ten No. 1 iron wires (0·3 in. diameter) laid helically round it, so as to give the whole the outward appearance of a simple wire rope. The completed cable weighs about six tons to the statute mile.

In subsequent cables, of which many specimens are exhibited, the single copper conducting wires have been sometimes replaced by strands of copper, to avoid the risk of a solution of continuity inside the gutta-percha, and to obtain greater flexibility. The quality of the gutta-percha has been lately much improved, and it has been combined with a varnish known as Chatterton's compound, which possesses some valuable properties. The dimensions of the copper and gutta-percha have been in some cases much increased: sometimes only one insulated conductor, and sometimes as many as six have been used. Sometimes large wires, and sometimes smaller

* The names of exhibitors who have received medals will, in the following report, be marked with the letter M. at the beginning of the description of each object exhibited by them. Those who have received honourable mention will be similarly marked by the letters H. M. The writer has adopted this plan after much consideration, for the following reasons:—The wording of the awards, necessarily short, by no means expresses fully or exactly the merit of each exhibitor. The award occasionally mentions only general excellence, and occasionally special instruments with approval. If the reward were mentioned in connection with every instrument where general excellence is rewarded, and only in connection with the one instrument where special excellence is attributed, injustice would frequently be done. Still greater injustice would result from the omission of the award from all instruments where general excellence is conceded. The wording of the award can, moreover, be consulted at pleasure, when the reader wishes to know whether any given instrument has been specially mentioned.

† 6, Duke-street, Adelphi, W.C., Oct. 7, 1863.

Sir,—Will you allow me to correct an error in my Report to the jurors on Electrical Instruments. In page 49 it is said that the first practical submarine cable was *laid* by Messrs. R. S. Newall & Co. I should have said that it was in chief part manufactured by Messrs. R. S. Newall, after some portion of the work had been done by Messrs. Wilkins & Weatherly, but that it was laid by Mr. Crampton, assisted by Mr. Wollaston.

You might place this letter as a foot-note in large type at the proper place in the reprint with which you are honouring the Report.

Your obedient servant,

Fleeming Jenkin.

ones have formed the outer protection; these wires have been sometimes separately covered with hemp to lighten the cable, or conjointly covered with hemp and bitumen as a protection against rust; in fine, many slight alterations have been proposed and adopted, but nevertheless, the cable laid in the present year for the Electric and International Company between England and Holland is in all essentials the same as that first laid between Dover and Calais. So far as shallow water cables are concerned this type promises to remain as constant, and, it may be added, as successful, as that of our railways, adopted by George Stephenson.

The Submarine Electric Telegraph Company (United Kingdom, 2,971) now own five cables, the aggregate length of which is 835 miles, and these cables contain 2,575 miles of insulated wire. They exhibit specimens of each cable. The first has been already described. The second, laid by Messrs. R. S. Newall & Co. in 1853, between Dover and Ostend, is 80½ miles long. It has six insulated conductors similar to those of the first-named cable, and is covered with twelve No. 2 iron wires. The third and fourth cables, connecting England with Denmark, and England with Hanover, were laid by Messrs. Glass, Elliot, & Co., and their length and dimensions will be found in a subsequent table, C; finally, the Beachy Head and Dieppe cable, 80 miles long, has six conductors formed of No. 16 copper wire covered to No. 1 gauge, and protected by twelve No. 1 iron wires. This cable was made in 1854 for a line between Sardinia and Algiers; part of it was lost in an unsuccessful attempt to carry out the line, and the remainder was laid by Mr. W. T. Henley in 1861 across the Channel.

Glass, Elliot, & Co., M. (United Kingdom, 2,900), show a large case filled with specimens of cables successfully laid by them in deep and shallow water. Altogether these specimens represent nearly 4,000 miles of cable, containing more than 6,700 miles of insulated wire, all successfully laid, and, with very insignificant exceptions, all now at work. A list of these cables is given in the following Table.

Table A.—List of all the Submarine Telegraph Cables Manufactured and Laid Down by Glass, Elliot, & Co., London.—October, 1862.

Date when laid.	From	To	Number of Conductors.	Length of Cable in Statute Miles.	Length of Insulated Wire in Statute Miles.	Period of Working.
1854	Sweden	Denmark	3	12	36	8 years.
1854	Italy	Corsica	6	110	660	8 years (deep sea).
1854	Corsica	Sardinia	6	10	60	8 years.
1855	Egypt	— — —	4	10	40	7 years.
1855	Italy	Sicily	1	5	5	7 years.
1856	Newfoundland	Cape Breton	1	85	85	6 years (deep sea).
1856	Prince Edward's Island	New Brunswick	1	12	12	6 years.
1857	Norway across	Fiords	1	49	49	5 years (deep sea).
1857	Across mouths of	Danube	1	3	3	5 years.
1857	Ceylon	Mainland of India	1	30	30	5 years.
1858	Italy	Sicily	1	8	8	4 years.
1858	England	Holland	4	140	560	4 years.
1858	Ditto	Hanover	2	280	560	4 years.
1858	Norway across	Fiords	1	16	16	4 years (deep sea).
1859	Alexandria	— — —	4	2	8	3 years.
1859	England	Denmark	3	368	1,104	3 years.
1859	Sweden	Gottland	1	64	64	3 years.
1859	Folkestone	Boulogne	6	24	144	3 years.
1859	Liverpool	Holyhead	2	25	50	3 years (out of working order).
1859	Across rivers	in India	1	10	10	3 years.
1859	Malta	Sicily	1	60	60	3 years.
1859	England	Isle of Man	1	36	36	3 years (out of working order).
1859	Jersey	Pirou, in France	1	21	21	2½ years.
1860	France*	Algiers	1	520	520	2 years (deep sea).
1860	Corfu †	Otranto	1	90	90	2 years (deep sea).
1861	Norway across	Fiords	1	16	16	1½ year (deep sea).
1861	Toulon	Corsica	1	195	195	1½ year (deep sea).
1861	Malta	Alexandria	1	1,535	1,535	1 year (80 knots, deep sea, 1,150 knots shallow).
1862	Abermawr, Pembroke	Grenore, Weyford	4	63	252	16 months.
1862	England	Holland	4	130	520	2 months.
				3,929	6,749	
		Deduct broken		61	86	
				3,868	6,663	

They are all of the usual type, except the France-Algiers* and Toulon-Corsica cables. These deep-sea cables were covered with steel wires, each of which had a serving of hemp applied with such a lay as materially to strengthen as well as lighten the cable.

This form would deserve a much fuller description than is here given, were it not for the fact that it probably will not again be used, in consequence of the attacks made by a species of teredo on the hemp. Messrs. Glass, Elliot, & Co. also state that it was found liable to kink.

The teredo consumes the hemp with great rapidity, leaving a mere bundle of loose wires round the core, which cannot then be lifted for repairs. These animals have also attacked the gutta-percha, and although hitherto they have not been known to make any very deep impression on it, their presence is certainly to be avoided as one source of danger. They are found at all depths, but have never been known to lodge in hemp under the usual iron covering; a few inches of loose hemp is sufficient to determine their presence in some seas.

The iron wires of the Isle of Man cable, and of the Wexford cable, are protected against corrosion by a compound of bitumen and hemp patented by Mr. Latimer Clark. This protection is fast coming into favour. The Malta-Alexandria cable, laid lately under the superintendence of Messrs. Gisborne & Forde for the English Government, is remarkable for its great length, the large dimensions of the insulated wire, and the perfect success with which it has worked since its submergence.

* In laying this cable it became necessary on two occasions to recover or pick up in the deepest water several miles of cable which had been submerged. On one occasion, when about thirty miles off Cape St. Sebastian, in a depth of 1,250 fathoms, and very rocky bottom, sixteen miles of cable were recovered, a fault cut out, and the cable relaid with perfect success. It has failed (temporarily at least) since writing the above.

† The end of this cable was lost in 450 fathoms off the Island of Fano, near Corfu. It was grappled for and recovered, and the line completed.

(To be continued.)

THE CONSTRUCTION OF TELEGRAPH LINES.

As, in consequence of the publication of Mr. Culley's book, considerable attention is being called to questions of construction and insulation, it may not be uninteresting to show what changes have actually taken place, or are impending in these respects.

The United Kingdom Telegraph Company have erected great lengths of line within the last three years, and there are some specialities in their mode of construction which appear noteworthy, and seem calculated to be beneficial in their operation. Thus, about three years ago, on the recommendation of Mr. Andrews, the manager of the company, the system originally in use of earth wiring, was changed:— Instead of carrying wires direct from the bolts of the insulators to the earth, which must greatly diminish the resistance, wherever there is loss or defective insulators, and necessarily create a maximum loss, the earth wire is bound three times round the arm, near the pole; any escape from the insulator is intercepted on reaching this point, and prevented from passing to other wires to make contact, and thus, as in the former system of earth wiring, only loss has to be overcome, and this is far less troublesome than what is technically known as weather contact. This loss or escape, too, is left at its natural figure, and not unnecessarily augmented, as is the case when the earth wire is taken directly to the bolt. Great care is also taken with the arrangement of the earth wires on the poles, to secure a good conducting surface, for what may not inaptly be termed "the intercepting system."

The company also early discovered that, to secure good and reliable working, the wires must be kept long distances apart, and for the last two years and upwards, the company has been carefully carrying out this policy, wisely, we think. The vertical distance, for instance, between the arms, is 10 and 12 inches, and the horizontal distance, from centre to centre of the insulators, from 22 inches up to 28 inches. Hence the probability of metallic contact, between the wires, is reduced to a minimum, and more work is thus got out of a small number of wires, than there would otherwise be obtained out of a large number erected upon the old plan.

These are practical points of interest to those engaged in constructing or carrying out telegraph lines, and we are not aware that these changes have been earlier carried out by any other company.

THE NEW TELEGRAPH.

The practice of the electric telegraph has been so successful that the public have almost lost any regard for the theory upon which it is based, and content themselves with the knowledge that they can for a shilling send twenty words from Liverpool to London; and the feeling of congratulation with which the discovery was welcomed has now become obliterated by one of unreasonable expectation, the only consideration being that each individual must have his message transmitted at once and delivered immediately. The public neither know nor care more than that a current of electricity passes from here to there, and makes some intelligible signs.

A rapid succession of beautiful inventions, each of which presented some new feature, has palled the appetite for wonders: and after seeing the latest improvement in type-printing telegraphs, nothing more seems required, and curiosity has gone to sleep. There is, however, now in Liverpool, and in operation at the Electric Telegraph Company's Offices in Castle-street, an instrument which, from its ingenuity of construction and perfection of results, deserves most careful attention. The object is to transmit autograph messages in the exact form in which they are written; and the most complicated figures, designs, sketches, or indeed anything that can be drawn by an ordinary pen, is transmitted as readily as the simplest dot or stroke. The instrument may be described as consisting chiefly of an iron frame, resembling the letter A, within which a heavy pendulum vibrates. About half way up one side of the frame an axle is placed transversely, and connected by an arm below and a rod to the pendulum, so that every vibration of the pendulum rocks this axle to and fro for about one-third of a circle. On the upper side of the axle, and at each end of it an arm is affixed, carrying a bent pointer or tracer, which runs over and in contact with a brass plate, curved to suit the radius of the arm. The message or sketch to be transmitted having been written upon foil paper with an ordinary pen, it is placed upon one of these tables, a piece of prepared paper being similarly placed upon the distant instrument intended to receive the message, the pendulum is set in motion, and the pointer makes a traverse across the plate of foil upon which the message is written. At all the points of contact with the metal a current of electricity continues to pass through the instrument; but where the ink intervenes the current is broken, and a corresponding interruption takes place on the distant machine by means of a rack pinion and screw, all worked by the pendulum. The pointer traverses over the whole plate in twenty minutes, and in that time would transmit as many words as could be written upon half a sheet of letter paper. The smaller the writing, therefore, the better.

At the return stroke of the pendulum the pointer on the second table comes into operation; thus two messages are transmitted at the same time by alternate vibrations, and at the turn of each stroke the pendulum bob comes in contact with a magnet, which maintains its motion, and communicates a similar one to the distant pendulum, thus correcting the isochronism and ensuring coincidence in the figure transmitted.

The principle of transmitting written messages is not new; but former inventors used a barrel driven by clockwork as the table for the paper, and although perfect results similar to these could be obtained, the liability to error in the rate of two clocks, and the difficulty of getting an apparatus sufficiently delicate to repeat currents rapidly, has prevented their economical use.

The most beautiful parts of this instrument are the relay coils and the automatic connections, which overcome these great difficulties so well, that the pointer may pass over a dozen or twenty words in a second, and the breaking and closing of the circuit will be complete for every letter. The influence of such improvements as these upon the commercial world are great, and may be judged from the fact that, in the London office of the Electric Telegraph Company alone, there are a dozen machines and operators for Liverpool work only.

If a company can, by rapid instruments, use one wire instead of two, one servant instead of two, and save transcribing in addition, the public will soon find the advantages of such inventions as these, which we concientiously believe to be destined to supplant the slow and unintelligible dot and stroke.

The only difficulties remaining to be overcome, so far as we can see, are—the great one of people writing their own messages so that they can be read, and the risk of the extremely delicate relay apparatus in its rapid vibrations being effected by atmospheric electricity.

We cannot say if this is fully achieved by Mr. Casselli; but we presume it is, for the apparatus has worked in Paris for ten years, and is, beyond doubt, the nearest approach to a perfect telegraph that we have seen.—*Railway News.*

COLONIAL TELEGRAPHY.

A very interesting report has just been published, giving an account of the electric telegraphs in Australia. In his financial speech Mr. Smart quoted one passage from this report to show the encouraging financial prospects of this investment. The telegraph is one of the few Government speculations which pay, and its success is an illustration of the over caution which capital sometimes displays in venturing on new enterprises. To have connected Melbourne and Sydney was a very proper enterprise for a private company. Yet capitalists would not look at it. Government was obliged to take it in hand, and when completed it was found to be very remunerative. The rapid multiplication of branch lines reduced the original dividend, but now it is beginning to rise again under the influence of the large trade that they create. For the last three years there has been a steadily increasing return. In 1860 the net revenue was at the rate of 5⅝ per cent. per annum on a capital of £48,500. In 1861 the net profit was at the rate of 6 per cent. on an invested capital of £60,000. In 1862 the net profit was at the rate of 7¾ per cent. on an invested capital of £116,235. This latter sum includes a charge of over £12,000 for building stations. This is a very satisfactory result, and is an encouragement to proceed with the extension of branch lines. That the telegraph makes business for itself seems proved by the fact that the branch lines pay better after the first year, when people have got accustomed to using them. It would be possible, of course, to overdo these extensions in a financial sense, but the Government is taking precautions against that by asking a guarantee of 5 per cent. interest from the residents in those districts that desire to have the telegraph. The cost of the telegraph is so slight compared with the convenience, that this guarantee is not onerous. The contract price for constructing new lines ranges from £38 to £50 a mile. The cheapest line was that from Campbelltown to Kiama *viâ* Wollongong. The total length of telegraph now in use is

2,174 miles, and, as for some distance there is a double wire, the length of wire is 2,539 miles. We have not only more extent of telegraph than any of the neighbouring colonies, but ours is the only colony in which it is a paying investment. Mr. Cracknell refers to the proposal which has been made to reduce the charges, but deprecates it as certain to lead to a loss of revenue, and argues that the public will be better accommodated by an extension of the lines than by a diminution in the charges.

Besides asking a private guarantee for rural extensions, the Government now offer to construct private lines to coal mines, or other large establishments, and work these lines at a charge of 5 per cent. on the outlay added to the cost of messages sent over the public line. At Bellambi this plan has been accepted, and it is expected that the Newcastle companies will also avail themselves of it.

The telegraphic money-order system did not pay, at which we are not surprised; the convenience was great to those who used it, but the occasions for its use were not likely to be very frequent. It is comparatively seldom that the payment of money is so urgent as not to wait the post. The telegraph, however, can still be used to secure the prompt payment of an ordinary postal money-order, if the sender thinks proper to go to the expense of sending the necessary message.

Wind and weather reports are daily received by telegraph from eight meteorological stations in the colony. Mr. Cracknell suggests that the number of these stations should be increased; and, furthermore, he suggests the adoption of the English plan of hoisting warning signals along the coast indicating the direction of coming gales. This, of course, would add to the expense of the department, without bringing in any income, but it might be the means of saving many lives, and much property.

Adverting to the Indo-Australian telegraph, Mr. Cracknell suggests that the colonies should jointly guarantee the funds for assisting Queensland to carry the line to the Gulf of Carpentaria. Since the date of his report, however, the Queensland Government has superseded this proposal by boldly proposing to undertake the whole work on its own account. The sum of £180,000 has been placed on the Estimates for that purpose, the design being to coast northwards as far as Port Denison, and there to strike across to the Gulf. The Parliament has not yet assented to this estimate. It is a bold undertaking for so young a colony, but there can be no doubt that it will prove indirectly, if not directly, remunerative. It would certainly precipitate the colonisation of Northern Australia. The only doubt we have as to the policy of the Queensland Government relates to the route chosen. Instead of clinging to the coast for so far northward as Port Denison, it would seem a more likely course to facilitate the occupation of the interior if the line struck inland through the fine pastoral territory now known to exist. In the course of a few years, however, there will probably be lines by both routes.

We have heard but little lately of the progress of the Anglo-Indian telegraph, but the preparatory work is going steadily forward, and before very long we may be startled by hearing that Calcutta is in regular communication with London, and by finding that our mail steamers, on leaving Galle, can bring away with them English news only three days old. The popular impression of the feasibility of connecting London with Sydney will then be quickened. But those who can forecast events can already see that it is by no means too soon for Australia to be preparing itself. The Queensland Government is not premature in the proposal it is making. Two or three years will probably be required for the accomplishment of the work, and by the time it is finished the junction with Batavia might, with proper arrangements, be contemporaneously completed. It has been suggested that a telegraphic communication between Sydney and Asia, north of the line, would greatly assist the development of our coal fields, and be an advantage to us independently of the benefit of being connected with Europe. There is very little doubt that this would be the case, especially if the projected line from Singapore to China is carried out.

LAW INTELLIGENCE.

THE SUBMARINE TELEGRAPH COMPANY *v.* DICKSON.—This was an action brought by the plaintiffs against the defendant, the owner of a Swedish ship, for so negligently casting his anchor when in the Channel, off the Kentish coast, that he caught, got entangled with, and damaged the plaintiffs' cable. The defendant, in substance, pleaded that he was lawfully navigating his ship, more than three miles from the coast, and that he had no notice that the cable was where he cast anchor. The plaintiffs now assigned that the defendant so negligently disentangled his anchor from the cable when he knew it was there, that he damaged it. There was another replication that the soil was the Queen's, who had given him licence to lay the cable there, in answer to a plea averring that the accident happened on the high seas, where the Queen had no jurisdiction, the ship being a Swedish ship. Both declarations and pleas were demurred to. Mr. R. Clark appeared in support of the declaration, and argued for the plaintiffs, and Mr. Archibald for the defendant. The Chief Justice thought the declaration good which charged damage to the plaintiffs by the negligence of the defendant. He assumed that the bottom of the sea might be used for lawful purposes as well as the surface. Of that the Court might take judicial notice, there being Acts of Parliament on the subject of submarine cables. The plaintiffs had a right to use the bottom of the sea, and to place their cable there. The defendant had a right to use the surface of the sea for the ordinary purposes of navigation, and to let go his anchor if the need of navigation required it. The two rights happened to conflict; the plaintiffs' property was damaged and their right violated by the defendant breaking their cable with his anchor. The defendant said, "I have a right to let go my anchor." Then came the replication, "You might have had that right, provided you had exercised it with due care and skill; but you had no right at all to damage our property." The whole essence of the case turned on the word "negligence." "If you had used due skill and care the damage would not have arisen." Mr. Justice Williams concurred. Mr. Justice Willes said, the defendant was bound to use reasonable care in so dropping his anchor as not to foul the cable. The declaration was good, the plea good, the second replication good, the third replication bad, as traversing immaterial matter.—Judgment for the plaintiffs.

CORRESPONDENCE.

MR. ANDREWS' PNEUMATIC APPARATUS.

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—I must confess my extreme surprise and pain to see in your journal of this day a statement by Mr. France, the present acting-engineer of the Submarine Telegraph Company, that he furnished the plan for my Pneumatic Apparatus described in the first number of your journal, and that I had the instrument manufactured on his plan without modification, I being the then engineer to the Company, and that not the slightest alteration was ever made in his original suggestion.

I am compelled to give to this statement the most unqualified and the most direct contradiction.

The idea of the Pneumatic Apparatus, with numerous other means of effecting the same object, namely, an instantaneous descending movement without resistance, combined with a graduated ascending movement, with the necessary "breaks" and "makes" of connection by one piece of mechanism, for submarine telegraphic purposes, originated solely with me.

A Mr. Banks, who was at the time mechanician to the Submarine Company, had the most to do with carrying out my plans in constructing this and other apparatus, which I mooted before I engaged Mr. France; the latter simply at one period conveyed my instructions to the manufacturer, and did not make one single suggestion of any kind whatever in relation to the construction of this or any of my apparatus.

I, of course, only claim my own forms; there are other instruments for effecting the same objects—those, namely, of Mr. C. F. Varley, and of Messrs. Siemens.—I am, Sir, your obedient servant,

W. ANDREWS,
Late Engineer to the Submarine Telegraph Company.

Melbourne Cottage, North Brixton,
London, 20th Jan., 1864.

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—I have seen a letter signed by J. R. France, and stating that he is the inventor of the Pneumatic Adjustment for working submarine cables. I was mechanician to the Submarine Telegraph Company at the time these pneumatic instruments were suggested, and the suggestion and the entire working out of them was proposed by Mr. Andrews, the former engineer to the Submarine Telegraph Company, before Mr. France returned from the Mediterranean and was engaged by the Company.

The instrument was solely Mr. Andrews', the then engineer, who gave all the instructions, and Mr. France had nothing to do with originating the instrument, and made no suggestions at all about them, and I can answer for it that Mr. Andrews was alone the inventor.

The manufacturers, who were always to and fro with Mr. Andrews and myself, would, I am sure, bear this out.

This was one of three or four instruments to do the same thing which Mr. Andrews at the time invented.—I am Sir, your obedient servant,

St. John's Wood, Jan. 19th, 1864. JAMES BANKS.

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—I have seen a letter in the *Telegraphic Journal* about Mr. Andrews' Pneumatic Arrangements; these were first talked of before Mr. France joined the Submarine, and all my negotiations about them were with Mr. Andrews, who explained the principle and gave all instructions about them; they were a long time in hand, with other apparatus designed by Mr. Andrews, who was trying several at the time, and in all these cases, including the pneumatic, Mr. Andrews it was who originated and carried them all out.

Mr. France saw me afterwards about making the Relay Pneumatic Arrangement; also for the key, acting, as I understood, under Mr. Andrews' instructions; but the instrument was no doubt designed and invented by the late engineer to the Submarine Telegraph Company, Mr. Andrews.

I am, Sir, your obedient servant,

GEORGE GUY,
Manager to the Manufacturer.

39, Windsor Terrace,
London, 19th Jan., 1864.

THE BONELLI'S TYPO-ELECTRIC TELEGRAPH.

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—Grateful as I am to your correspondent for the very complimentary way in which, as people in post-prandial orations say, he has mentioned my name, I feel that the public has so little interest in the exchange of epistolatory amenities, that I shall, without apology, address myself to that portion of "J. P.'s" letter which demands an answer.

It happens curiously enough that the point which "J. P." considers the weakest in the Bonelli system is precisely that which I esteem the strongest, and I venture to think by the aid of a few plain figures I can prove that I am right.

The impression conveyed by your correspondent's letter would be that the telegraphic transmission (warm from the lips of fervid eloquence) of the words (upon which a nation hangs) is effected without pause or intermediations; that the manipulator of the instrument catches the inspired sentences as they fall, and flashes them with kindred fire and rival rapidity along the wire. Alas, the case is far otherwise—much more prosaic and laborious. It is, as I understand the matter, thus:

An accomplished stenographer takes his place, the orator opens his lips, and fast as the honied or embittered words, the learned aphorisms or the logical deductions fall, they are written down in those marvellous, and, to the mass, incomprehensible symbols which constitute "short-hand." To the writer, and to the writer only, these notes are as an open book, and, consequently, at the expiration of a given time—some half-hour or twenty minutes—this gentleman gives place to another reporter, and while the matter is fresh and vivid in his mind, reproduces, by a combined effort of memory and imagination, the speech of the orator, and transcribes these calabastics into characters which are potent to the vulgar eye. Up to this point all systems are in abeyance. The transcription is handed as fast as it can be written to the Morse clerks or Bonelli type-setters; starting, therefore, as we do, fairly from this point, let us compare the two systems with each other.

For this purpose I propose to take two instances which have been much insisted on as evidences of the rapidity of Morse signalling: the recent speeches of the Emperor of the French, containing respectively 2,044 and 1,316 words, were transmitted from Paris to London, the former in an hour and a quarter, the latter in twenty minutes; in the one case two wires were employed, in the other four, thus giving an average seven words per minute for each clerk employed. These 3,360 words were transmitted in one hour and thirty-five minutes; an equal number of compositors could set this number of words in type in thirty-seven minutes—ten minutes more would suffice to transmit the whole clearly printed in permanent plain Roman characters, making a total of forty-seven minutes; showing a clear gain of forty-eight minutes, not to mention the important fact that in the one case no translation or transcription, with all the consequent liability to error is required, while in the other, every word must be reduced first from written to conventional signs, and then from conventional to ordinary characters before it reaches the hands of the printers. It happens, however, that the speech of the Emperor, and all similar discourses, are handed beforehand to those interested; and thus, although it is not etiquette to commence transmission before the last word has died upon the lips of the speaker, the type might of course, without breach of propriety, be set up, in this case it being unnecessary to use a permanent solution; three minutes later the entire speech, punctuated and perfect, in the form most easy for recomposition, would be in the hands of the type-setters in Printing-house-square. "J. P." appears to forget that with an instrument capable of transmitting, by the aid of a couple of boys, 72,000 words per hour, the whole staff of the company—or, rather, of an office—would be available; or, to meet some special emergency, a dozen extra type-setters could be called in, so as to reduce the time to an almost indefinite extent.

With the Bonelli system the sole limit to rapidity is imposed by the time occupied in translating and writing out the short-hand notes. Let the reporter be replaced every ten minutes, and let it occupy him twenty minutes to transcribe his ten minutes' work, there is no earthly reason why the longest speech should not be in print in Manchester or any other place thirty minutes after an orator in London ceased to speak; and as the same type would of course serve for any number of transmissions, the whole would be delivered in every city to which the system is extended three seconds later in each succeeding case. I feel these few remarks will suffice.

I smile at "J. P.'s" idea that these marvels can be accomplished with one wire. All single wire instruments must be either synchronous or slow, such at least is my rooted conviction; and I have so often thought on the question till my head ached, that I have determined to consider the question at rest till I see some proof that I am wrong.

Kind friends are continually assuring me that the great electrical authorities of England persist in ignoring the merits of Bonelli's instrument, saying (that there is nothing in it) that it will not answer, &c. I would be so grateful if some of those gentlemen would leave such weak generalities and tell me and the world they guide upon what possible grounds they base their assertions.—I am, Sir, obediently your servant,

7, Angel-court, City. HENRY COOK.

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—Your correspondent, "J. P.," in the last number of your journal, seems to have an imperfect knowledge of the transmitting powers of the *Morse* instrument. The transmission through that instrument scarcely ever exceeds 25 words per minute, and the words, being formed of *dots* and *dashes*, must be transcribed into common handwriting before the matter can be placed in the printer's hands, which occupies considerable time. While with the Bonelli typo-telegraph the reporter at the House of Commons, or at any public meeting, delivers his copy into the hands of some dozen or more expert compositors, whose galleys are *combed over*, as it were, as rapidly as they can be placed in the telegraphic machine, the matter appearing at the distant end *printed*, and is transferred at once into the hands of the printers at the newspaper-office. The strips may be divided among any number of printers as occasion may require; and, as the instrument is capable of transmitting words at the rate of 72,000 per hour, I see no reason why we should not have the words warm from the "fervid lips of eloquence" as soon as the wires are carried down south.

Yours obediently,

Manchester. A MORSE MANIPULATOR.

RESISTANCE COILS.

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—Mr. Fleeming Jenkin, in his report of the jurors' decisions in Class XII., which appeared in your last number, states that no resistance coils were exhibited in 1851—meaning, I presume, the International Exhibition which took place that year—but that "Professor Wheatstone's rheostat and resistance coils had been described in the *Philosophical Transactions* as early as 1843." I have had opportunities of making several experiments, in the carrying out of which I employed the identical instruments above referred to with far greater success than with any instrument of modern construction; but what I am anxious to know is, when was the system of measurement by resistance coils first introduced, and by whom, into practical telegraphy? The resistance coils are now extensively employed by electricians in every part of the globe; but I have heard the merit of their first introduction attributed to so many individuals that I am desirous to learn to whom the honour is really due. Yours, &c.,

A SUBSCRIBER.

TELEGRAPH EMPLOYÉS.

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—In your first number you promised to devote a portion of your space every week for the benefit or instruction of the student and amateur. I noticed also in the same number a letter signed "J. R. O.," referring to the notion which seems somewhat prevalent, that telegraph clerks, as a rule, are but an ignorant, ill-informed class in the matter of telegraphic and electrical knowledge. I know not if it be true that we are so far below the status of continental clerks in this respect; but I *do* know that a great many of those in the service of our large telegraph companies have no means of acquiring such knowledge save that afforded them by the pages of a cheap, popular serial like the *Telegraphic Journal*. The simplest and rudest apparatus for the conducting of electrical experiments costs more money than most ordinary clerks can afford, who enter upon that vocation as a means of earning a livelihood, and there are scores of these individuals who remain in the service for years without materially bettering their circumstances; they form connections for life, and little ones rise up depending upon their not over-abundant earnings for support; and this is the tendency of mankind in all circumstances, prosperous or otherwise, however Malthusians may rate; and hence these otherwise very deserving individuals are literally debarred from making any extraordinary advance in the knowledge of the glorious science of which they are, so to speak, the humble exponents. I well remember a case in point some six or seven years since when I had occasion to reside in a not very large town in the Midland Counties. It boasted of but one telegraph station, the duties of which were performed by one clerk, whose salary amounted to but a trifle over 20*s.* per week. Out of this he had a family of three children to provide for, and a faithful spouse, who, I'll warrant, would not stop short of a dozen such blessings. I never witnessed that worthy individual striving to look respectable in a threadbare coat, for which no tailor ever took his dimensions, and his shoes polished like a nobleman's, although sadly down at heel, decorously taking his Sunday afternoon's walk, carrying the baby, while Materfamilias and the two little Dames Trot trudged along by his side, but what I always experienced a mingled feeling of pity and admiration.

The ancient philosopher tells us that an honest man struggling with adversity, and withstanding the temptations incident to the situation, is a spectacle which excites the admiration of the gods, and upon which they look down with peculiar favour. But, alas! if the gods should do no more than this for a telegraph clerk who is poor, and yet too honest to mend his circumstances by other than the strictest rules of rectitude, he will make little attainments in electrical science this side the Olympian Mount.

A man with limited means may make vast strides in self-culture in any department of science, art, or mechanics, as long as he remains single; but let him once pay his devotions at the shrine of Hymen, and there is pretty sure to be an end of it, unless the goddess of prosperity makes her advent at the same time.

Now, it is quite certain that every clerk in the service cannot reasonably expect to be the recipient of a windfall; hence the majority must ever remain at best but just respectable citizens, who, when they have paid their way on Saturday night, have little left for extras, and nothing for superfluities. How is this important class to progress in knowledge and attainments of a science of which it is impossible to acquire any practical information without considerable expense? And how is the stigma to be removed, whether just or unjust, under which they lie? For myself, I believe it to be a cruel and unjust aspersion. I would ask, in what country in Europe is the work of a telegraph company more efficiently performed than it is in those lines worked by English clerks? And surely this should be esteemed proof positive that such an assertion is unjust and utterly destitute of foundation. Nevertheless, every one must admit there is room for improvement. Telegraph clerks cannot know too much of the mysteries of the science; and a thorough acquaintance with the numerous and diverse instruments used in its development is no less indispensable. We look to you, sir, therefore, to render us that step by step information which shall bring us up to the same point of electrical and telegraphic attainments as that which characterizes the first electricians of the day; and then if we fail to profit by the same, and do not excel our former selves and our bearded cousins of Gaul and Vaterland, may we suffer the full measure of just reproach, and be stigmatized as unworthy the vocation which we ought to adorn. I have been expecting your first instalment for students and amateurs, and so, I know, have many others. Pray do what you can to render necessary information in a popular and understandable form. Let us have descriptions of instruments, and so forth, which have made their inventors famous, but of which, alas! we know nothing; and every other description of knowledge which it is essential we should know.

A CITY TELEGRAPH CLERK.

TELEGRAPHIC NEWS.

THE Electric and International Telegraph Company are constructing an additional pneumatic apparatus between their chief station in Telegraph-street and the branch establishment in Leadenhall-street. The pipe is 2½ inches in diameter, and we believe that considerable improvements have been recently effected in the method of working the pneumatic pipes now being laid.

DURING the last year the construction of the telegraph for military services in the United States has been very greatly extended. There is now in operation and connected with the military department not less than 5,326 miles of telegraph; of these, 1,755 miles of land and submarine lines were constructed last year. The Secretary of War reports that not less than 1,200,000 telegrams, on an average 3,300 per day, have been sent over these lines. The messages so sent varied from 10 to 1,000 words, and were for the most part of an urgent or most important character.

THE progress of the Electric Telegraph in Russia during the last few years has far exceeded that of any other country, especially when we consider the enormous difficulties the contractors and engineers have had to contend against in constructing their lines over hundreds of miles of inhospitable and barren steppes, and across regions inhabited by people in a state of semi-barbarism, where the poles and wires are protected by having the sacred cross suspended to the wires or affixed to the poles. Lines from St. Petersburg and Moscow now penetrate into the penal solitudes of Siberia, and have reached the frontiers of China, and are rapidly progressing towards the Amour, along the banks of which they will extend to join the proposed submarine line, uniting through Russian America, St. Petersburg, and New York by means of the San Francisco telegraph. Several contracts have been recently entered into by English houses for the construction of lines in the interior of Russia, amongst whom we may mention Messrs. Siemens, Halske, & Co., and Messrs. W. M. Warden, & Co., of Westminster, the latter firm having, we understand, entered into an arrangement for the construction of a double line of telegraph on the Dünaborg and Vitebsk Railway—a distance of 160 miles.

BY the latest intelligence from North-West British America we are pleased to learn that Professor Hind was to have read a paper on the commercial resources of the Lake Winnipeg and Saskatchewan districts in Central British America, at the rooms of the Statistical Society, on Tuesday, the 19th instant. Professor Hind had just arrived from Canada, and placed before his auditory the latest intelligence respecting the territory he explored, under instructions from the Canadian Government, in 1857 and 1858. The recent reorganisation of the Hudson's Bay Company would give prominence to any additional information that can be made known regarding North-West British America. Recent events in the State of Minnesota, whose northern boundary is conterminous with the Lake Winnipeg and Saskatchewan districts, render any information bearing upon commercial progress there peculiarly opportune at the present juncture. Our readers are familiar with the splendid schemes for colonization and telegraphic communication recently put forth in the prospectus of the Hudson's Bay Company, but it is not generally known that important steps have already been taken by the citizens of Minnesota to secure to themselves the rapidly developing commerce of the "Great North-West." From all we can learn on the subject, the construction of the proposed telegraph across the continent through British America, under the auspices of the Hudson's Bay Company, can be accomplished without difficulty, as well as a postal communication by the route of the Canadian emigrants of 1862 from Canada to British Columbia. The more we know of the vast resources of this part of Central America the wider appears to be the field for commercial enterprise. So rapid is the progress of the settlement on the American continent that all the farm lots on the immediate bank of River Kaminishquia, at the head of Lake Superior, only lately brought into the market by the Canadian Government, are taken up by actual settlers, and where, at the utmost westerly limits of Canada half-a-dozen years ago, the forts of the Hudson's Bay Company and an Indian village afforded the only signs of civilization, there are now to be found hundreds of settlers clearing and cultivating the land and bringing the mineral wealth of that region into the market. Further North-West, in the valley of the Red River of the North, American settlers are flocking into British territory, tempted, no doubt, not only by the excellent quality of the soil, but by the prospective circulation of money which the construction of the telegraph and the opening of a postal route must ensure. After many years' delay we now begin to discern signs of activity on the part of those who have the interests of that vast region for a time in their hands. We say for a time, as it is certain that if energetic measures are not taken the course of events will be such as to bring about, under other auspices, the opening of the North-West, which has been too long delayed already. The title of the paper which Professor Hind is to bring before the Statistical Society leads us to hope that he will furnish such a view of the resources of Central British America as will not fail to direct public attention to that long-neglected country. Telegraphic and postal communication, under British control, between the Atlantic and Pacific, is a grand conception; but if it can be shown that the country possesses natural resources to sustain a line of agricultural settlements from sea to sea, the scheme then becomes one of national importance. We look forward with much interest to the delivery of the paper.

MISCELLANEA.

THE velocity of electricity is so great that the most rapid motion which can be produced by art appears to be actual rest when compared with it. A wheel revolving with celerity sufficient to render its spokes invisible, when illuminated by a flash of lightning, is seen for an instant with all its spokes distinct as if it were in a state of absolute rest. This beautiful experiment is due to Professor Wheatsone, as well as the following variation of it, which is not less striking. Since a sunbeam consists of a mixture of blue, yellow, and red light, if a circular piece of pasteboard be divided into three sectors, one of which is painted blue, another yellow, and the third red, it will appear to be white when revolving quickly, because of the rapidity in which the impression of the colours succeed each other on the retina. But the instant it is illuminated by an electric spark it seems to stand still, and its colour is as distinct as if it were at rest.

SOME attention has been directed to the enormous variation in electric conducting power, caused by the admixture of even minute quantities of metallic or other impurities in copper. It has become a question of some interest to determine the electric conducting power of all the pure metals. Professor Matthiessen has continued his researches on this subject, and has lately determined the electrical relations of pure thallium. At the freezing point of water this metal has a conducting power equal to 9·16 (pure silver being 100), and its conducting power decreases between the freezing and the boiling point 31·420 per cent., which is a larger percentage decrement than that obtained for many other pure metals—namely, 29·307 per cent. The conducting power of pure iron was found to be at 0° C = 16·81, with a percentage decrement for an increase of temperature to 100° C = 38·1. The conducting powers of the pure metals given in the following table shows the places which the above metals take in the series:—

	Conducting power at °.
Silver	100 00
Copper	95·95
Gold	77·96
Zinc	29·02
Cadmium	23·72
Cobalt	17·22
Iron	16·81
Nickel	13·11
Tin	12·36
Thallium	9·16
Lead	8·32
Arsenic	4·76
Antimony	4·62
Bismuth	1·245

THE ORIGIN OF THE TERM "VULCANIZATION."—Mr. Thomas Hancock, in his *Personal Narrative*, &c., gives the following explanation as to the origin of the word Vulcanization :—"In preparing to carry out the new process on a large scale, it appeared desirable to give the material a more definite name than the 'change' which I had adopted for the purpose of my specification; and, whilst discussing the subject amongst my friends, Mr. Brockendon proposed the term 'VULCANIZATION,' and, as no better suggested itself, I determined to adopt it, and it is now known by that name both in Europe and America. It owes its origin to the Vulcan of mythology, as in some degree representing the employment of sulphur and heat, with which that mythological personage was supposed to be familiar."

GUTTA PERCHA, the latter word pronounced *pert-sha*, is a gum, taken from a tree called by that name by the Malayans, in whose peninsula this tree grows. The natural order of the tree is *sapotaceæ*. It grows to a considerable height, and may sometimes be found more than six feet in diameter. The gum or juice is obtained by tapping; and it is stated that one tree will produce more than 30 lbs. weight annually. The most valuable property of gutta percha at the present day is that of its insulating powers, rendering it most valuable for telegraphic purposes, although its application for other purposes is still extensive.

IT has long been a desideratum among electricians to obtain a battery having the constancy of Daniell's without the annoyance attending the use of a porous cell. Two such batteries have been described lately. One is the invention of M. Jacobini, and consists of a glass vessel, in which is placed a cylinder of copper pierced with holes; outside this is a large cylinder of zinc. The copper cylinder is filled with powdered sulphate of copper tightly pushed down, and the remainder of the space in the glass vessel is filled with water, so as to saturate both the sand and the powdered sulphate of copper, and the arrangement is covered up. Several hours elapse before the electric current begins to develope itself actively. It then increases for a few days, and finally sinks again till its power becomes constant. Father Sechi has had a battery of this kind in use for three months, and reports that it is as efficient as when first constructed.

MR. FRANCIS RONALD, of Hammersmith, published a description of his electric telegraph in 1823. It was to consist of clocks showing letters, timed together, but wholly independent of each other, and wholly independent also of a line of wire which was to be insulated, in tubes of glass, between the two places where the clocks were respectively to stand. When the person desirous of sending a signal saw on his own clock the signal which he wished his correspondent to note on the distant clock, he charged the conducting wire by an electrical machine, which was to produce the divergence of two pith balls at the distant clock; and under the conditions of perfect coincidence of movement in the clocks, the warning to look for the signal might reach the correspondent at the right moment, whose attention was to have been secured by causing an electric spark to fire a pistol in the first instance. Mr. Ronald's was not a combined system of apparatus, constructed so as to work reciprocally, but three separate and independent elements of communication—viz., the two clocks and the line of insulated wire, arranged in a kind of partnership, for the purpose of producing a combination of effect by a coincidence of action.

ROYAL INSTITUTION LECTURES.—Professor Tyndall began a course of lectures on Electricity (adapted to an educated juvenile auditory) on Saturday, December 26, his subject being "Electricity at Rest, or Static," the leading principles of the science being abundantly illustrated by experiments. After a few introductory remarks on the importance of experiments as the means of investigating into the causes of natural phenomena, such as rain, snow, thunder, and lightning, Professor Tyndall proceeded to show that the simplest method of obtaining electricity was by friction, in the cases of dry glass rubbed by dry silk (with amalgam spread upon it), and of dry sealing wax and other resinous bodies, rubbed with dry flannel—the electrified bodies attracting and being attracted by unelectrified matter. The electricity produced on the glass is termed vitreous, and that on the sealing-wax resinous; but these names were shown to be incorrect, inasmuch as when the rubber was changed the electricity of the wax was produced on the glass and that of the glass on the wax. The electricity obtained from glass by friction with silk is now termed positive, and that obtained from sealing wax by friction with flannel is termed negative. The Professor demonstrated the fundamental law of electric action; that bodies charged with the same electricity repel each other, while bodies charged with opposite electricities attract each other:—Positive repels positive and attracts negative; negative repels negative and attracts positive. We cannot excite one of those electricities without at the same time exciting the other. When, for example, a body is electrified by friction, the *rubber* is electrified at the same time; and the electricity of the rubber is always the opposite to that of the body rubbed. It was shown that the substances termed conductors are those which permit electricity to pass freely through them, and that others, termed insulators, stop its progress. The theory of electric fluids, though quite hypothetical, was thus explained as being exceedingly useful in comprehending many phenomena:—Electrical attractions and repulsions are supposed to arise from two invisible fluids, each of which is self-repulsive, the two fluids being mutually attractive. Both fluids are supposed to be mixed together in unelectrified bodies. The act of electrifying by friction consists in the forcible separation of the two fluids: one of them is diffused over the rubber and the other over the body rubbed. Thus, when glass is rubbed with silk the positive fluid is supposed to cover the glass like a film; and when sealing-wax is rubbed by flannel the negative fluid is supposed to cover the wax like a film. The positive fluid repels the positive and attracts the negative; while the negative fluid repels the negative and attracts the positive. The body to which the fluid adheres is attracted or repelled with the fluid, and hence arises the attractions and repulsions which experiment reveals.—The second lecture was mainly devoted to experimental illustrations of the phenomena of induction. The theory of electric fluids supposes that the negative and positive fluids exist as one compound fluid in an unelectrified body. The Professor demonstrated that when an electrified body was brought near an unelectrified one, but not into contact with it, the electrified body decomposed the compound fluid of the unelectrified one; attracting one of its constituents and repelling the other. This forcible separation of the two fluids is termed "induction." When rubbed glass (which produces positive electricity) was placed near a wooden ball coated with tinfoil, the side of the ball next the glass was charged by induction with negative electricity, the positive being repelled to the other side, the mere proximity of the electrified body, without contact, charging the neutral body with the opposite electricity. The repelled electricity was free; but the attracted electricity (negative to positive or positive to negative) was held fast by the inducing body; but it was shown that, if such an induced body be connected for a moment by a conductor with the earth, the free electricity will escape; and that also, on the removal of the inducing body, the electricity formerly held captive will become free and the induced body remain electrified. The Professor next explained the principle of Volta's electrophorus, and extemporised a very cheap and efficient one—*i.e.* a small circular sheet of zinc, with a stick of sealing-wax for a handle, gutta-percha or vulcanized india-rubber being used as the plate to be excited by friction with flannel, &c. When the zinc was placed on the india-rubber, and then lifted by the handle, it was found to be charged with positive electricity. The lecture concluded with an explanation of electric condensation, being introductory to the study of the Leyden jar.—The third lecture was mainly devoted to experimental illustrations of the principle and action of the electric machine and the Leyden jar and battery. It was shown that, if we increase the quantity of electricity imparted to a conductor we increase the density of the electricity: that the density of the electricity on a sphere is the same at all points of its surface; that on a plate the density is greatest at the edges; and on an elongated conductor the density is greatest at the ends; and also that when this conductor ends in a sharp point the electricity at the point is so great that the electricity discharges itself into the air. The electric machine consists of two parts—the insulator, excited by friction, and the prime conductor. The Professor stated that the first electric machine, consisting of a ball of sulphur, which was rubbed against the hand, was invented by Otto von Guericke, Burgomaster of Magdeburg, in 1671. Afterwards a sphere of glass was introduced, then a cylinder of glass, and finally a round glass plate, which was rubbed with dry silk. Various forms of the electric machine were exhibited in action. When the glass plate of the large machine was turned by a handle, so as to cause it to pass between the silk rubbers, it was positively electrified. The electrified glass then acted by induction upon the prime conductor, attracting the negative electricity and repelling its positive. The conductor was furnished with points, from which the negative electricity streamed out against the excited glass. Thus the prime conductor was charged, not by directly communicating to it positive electricity, but by robbing it of its negative, the positive remaining behind. In the Leyden jar, the inner and outer sides of which are coated with tinfoil, the charged interior coating acts by induction across the glass on the outer coating, attracting the positive and repelling the negative electricity. By the escape of the latter, the jar takes a larger charge. A number of these jars, when connected with the machine and with each other, formed the Leyden battery; several of the powerful effects of which were exhibited, such as the vaporisation of silver wire. The Professor formed a Leyden jar by standing on an insulating stool, and clasping the hand of his assistant, placed on the ground, wearing at the same time a vulcanized india-rubber glove. When the machine was turned the two hands and glove formed a charged Leyden jar.—In the fourth lecture Professor Tyndall proceeded to show how two bodies oppositely electrified discharge to each other with a bright spark; he stated that, in like manner, when two oppositely-electrified clouds discharge towards each other, the track of the lightning marks the course of the electric current, and thunder is the sound of the spark. If the body through which the atmospheric electricity passes be a good conductor and of sufficient size, no harm is done; but the resistance to the passage of the electricity offered by trees, houses, and animals, frequently causes their destruction. Before proceeding to the illustration of the principles of Voltaic Electricity, or Electricity in Motion, the Professor exhibited the leading phenomena of magnetism, explaining the action of the magnetic needle as an indicator of the direction of electric currents. The construction of the voltaic battery was then shown in detail, and the deflection of the needle was produced by strips of zinc and copper dipped in acidulated water, and also from the same substances introduced into an apple and a lemon, and also by cutting a beef-steak by means of a knife and a silver fork. The voltaic battery is composed of a series of cells containing a liquid and two metals; and the wire proceeding from each end of the series of cells, when connected, forms what is termed the circuit. This connecting wire, when the current is

passing, becomes magnetic, attracting iron filings; and when the wire is coiled round a bar of iron, and a current of electricity is produced, the bar becomes a magnet. By this means magnets of enormous power are constructed sufficient to support the weight of many tons. In conclusion, the power of the great electro-magnet of the institution was exhibited, in its sustaining heavy weights, a scuttle of coals, and even the Professor himself.—The fifth lecture began with further explanatory illustrations of the law of the electric currents, showing that when two currents flow in the same direction they attract each other, but when they flow in opposite directions they repel each other; and proving that this was the case with the helix, or coil of wire, surrounding the core of the electro-magnet, as well as with the electro-magnet itself. He stated that some philosophers had gone so far as to suppose that electric currents circulate round the atoms of a magnet; and that magnetic attractions and repulsions are really due to the attractions and repulsions of these little molecular currents. The remainder of the lecture was devoted to the phenomena of electro-chemistry. All bodies are now supposed to be composed of atoms, the smallest particles into which matter can be divided: thus, the air is said to be a mixture of atoms of the gases oxygen and nitrogen; water to be made up of atoms of the gases oxygen and hydrogen, and common salt of the metal sodium and the gas chlorine. By the chemical action set up in the voltaic battery, due to the action of oxygen on zinc, it was shown that these various bodies could be broken up and their respective elements set free at the opposite poles of the battery. Our limited space prevents us from going further into the interesting details of experiments made during the researches within the walls of the Royal Institution, to which the world is mainly indebted for the remarkable applications of the electrotype, and important application of electro-chemistry. By means of the electric lamp several electro-chemical phenomena, such as the decomposition of water, the formation of the lead-tree, &c., were beautifully shown on a white screen.—Concluding lecture. Beginning with experimental illustrations of the phenomena of "induced currents," Professor Tyndall showed that when the two ends of a flat coil of covered wire were connected with a galvanometer (a magnetic needle surrounded by a wire), and a second flat coil was laid upon it, and the two ends of the upper coil were connected with a voltaic battery; the instant the current commenced to flow through the upper coil a current was excited in the under one, which was shown by the deflection of the needle. The direction of the current in the under coil was opposed to that of the current in the upper one. The current excited in the under coil, called an *induced current*, is only of momentary duration. The coil through which the current from the battery flowed is termed the "primary" coil, and that connected with the galvanometer is termed the "secondary." Both at making and breaking the circuit a momentary induced current was excited; that generated at making being opposed in direction to the primary, while that generated at breaking is in the same direction as the primary. Thus, also, when a magnetic pole was brought in contact with the secondary coil, a current was excited; and when the pole was withdrawn another current was excited. When a bar of iron was placed within a hollow coil, on touching the bar with a magnet the iron was magnetised and a current excited in the surrounding coil. On withdrawing the magnet the iron lost its magnetism, and an opposed current was excited in the coil. It was shown that, by multiplying the coils of the secondary, these induced currents could be raised to a high degree of intensity, and by making and breaking the primary circuit in quick succession, a correspondingly quick succession of induced currents may be obtained. This was proved in the apparatus termed the magnetic hammer. It is chiefly "induced currents" that are employed for electro-medical purposes. The latter part of the lecture was devoted to the exhibition of the light and heat developed by the voltaic battery. It was stated that the heat generated is proportional to the resistance overcome; hence, when a current passed through silver and platinum wires of the same thickness, the latter, being the worse conductor, is the most heated. It was also shown that a heated wire offers more resistance to the passage of the current than the same wire when cooled; and that, if we cool a wire rendered ret-hot by a current by plunging it into water, we diminish the resistance and augment the flow of electricity through the wire, and raise the uncooled part to a higher state of incandescence. Lastly, the Professor exhibited and explained the action of the electric lamp, emitting a light almost rivalling that of the sun, from which, by means of a prism, a most beautiful spectrum was produced. The course was concluded with remarks on the great advantages of scientific study as a branch of education.

TO CORRESPONDENTS.

SHACKLE.—The publication of your letter would not, we feel confident, effect the object you have in view.

HISTORIAN.—The first patent for "improvements in giving signals and sounding alarums in distant places by means of electric currents transmitted through metallic circuits" was granted to William Fothergill Cooke, of Breed's-place, Hastings, in the county of Sussex, Esquire, and Charles Wheatstone, of Conduit-street, Hanover-square, in the county of Middlesex, Esquire. It passed the great seal on the 12th June, 1837. The specification is of enormous length, occupying fifty-nine pages of closely printed matter, and the various parts of the apparatus are illustrated by upwards of forty diagrams.

J. F. B.—Your favour was received too late for insertion this week.

As information respecting Improvements, Extension of Lines, and Progress of New Undertakings will at all times be most acceptable, we hope that our readers will kindly render us assistance in our efforts to establish a Journal worthy in all respects of the great interest it seeks to represent, by furnishing us with brief notices of events and occurrences in connection with Telegraphy.

Communications intended for publication must be authenticated by the names and addresses of the writers; not neccessarily for insertion.

Letters relating to Advertisements are to be addressed to the Publishers. All other letters and communications to be addressed to the Editor of the *Telegraphic Journal*, 5, Suffolk-lane, Cannon-street, London, E.C.

The *Telegraphic Journal* can be had of Messrs. SMITH & Co., Strand; Messrs. DAWSON & Co., Cannon-street West; Messrs. KENT & Co., Paternoster-row, London. Messrs. HEYWOOD & Co., Manchester; at the various railway stations; and of all news-agents, &c., &c.; or it can be supplied, if preferred, direct from the Office on the following terms (paid in advance):—

	s.	d.
Quarterly	4	4
Half-yearly	8	8
Yearly	17	4

TO ADVERTISERS.

The *Telegraphic Journal* is the most effective medium for inventors, patentees, contractors, manufacturers of insulating materials and electrical apparatus to submit their various specialities to the consideration of secretaries and managers of telegraph or railway companies, and other persons engaged in electrical and telegraphic pursuits.

Clerks, assistants, manipulators, and instrument makers, seeking employment, &c., will find the *Telegraphic Journal* a ready means of making known their requirements.

Advertisements must be delivered to ensure insertion before SEVEN O'CLOCK on Thursday evening in each week. The charges for Advertisements are—

	£.	s.	d.
Whole page	4	4	0
Half ditto	2	10	0
Quarter ditto.	1	7	6
Four lines and under (single column)	0	3	0

Single Advertisements from the country must be accompanied with stamps in payment.

TELEGRAPHIC PROGRESS.

THE telegraphic operations of the past year contributed largely towards the development of the system both at home and abroad. The lines constructed are far more substantial and efficient than those constructed in preceding years. Valuable improvements were introduced and adopted, and the advantages derived therefrom have already justified the additional expenditure. The working of the lines has been more regular and certain, and a considerable saving effected in the amount of battery power. In the United Kingdom some hundreds of miles of new lines were erected by the various companies during the year, and many of the old lines, which had, from the wear and tear of time, been greatly impaired, were restored by the substitution of new wires and apparatus of improved quality and description.

The important subject of aerial, or what is generally designated pole insulation, at no period, perhaps, engaged the attention of telegraph engineers and electricians to a greater extent than during the past year; and several valuable improvements were effected in the old system, which have greatly contributed to the more economical and efficient working of long circuits. Although earthenware, porcelain, and glass insulators are still in demand and extensively employed, the appearance of a rival in the shape of ebonite has led to great improvement in their manufacture, shape, and size, which has greatly enhanced their value in practical telegraphy. In addition to these improvements in the science of telegraphy, various useful instruments have been contrived to ascertain the resistance presented by the conductor to the passage of the electric current, and for the detection of injuries and "faults," which must greatly tend to facilitate the labours of those entrusted with the management of our telegraphic lines.

We have also to notice the introduction of several ingenious and valuable "printing" instruments, such as Hughes', Bonelli's, Casselli's, and those distinguished as "alphabetical," by Wheatstone, Henley, Wilde, and others, which in time must effect a great change in the transmission of intelligence from place to place by the rapidity with which it can be accomplished.

Submarine telegraphy, which had long suffered undeservedly from "instructive failures," made a great step towards regaining public confidence. The Atlantic Telegraph Company, with renewed energy, determined to make another effort to realize the great object for which it was formed—the uniting of the Old and New World. Although matters, to all appearance, progressed favourably—the necessary capital subscribed, the form of cable decided upon, the contractors' tender accepted, and a decision arrived at to submerge the cable in 1864,—from prudential motives, as we readily believe, the great work has been postponed until next year. Another cable of considerable political and commercial importance left our shores to be laid in the Persian Gulf, to form one of the great telegraphic links of communication between England and its eastern possessions. In its construction all the most recent improvements have been adopted in the preparation of the copper, in the application of the insulating material, and in the furnishing of a protective sheathing and its protection from oxidation.

Indications already abound that the present year will be an "eventful one" in both land and submarine telegraphy. Several extensive projects are spoken of, and are only held in abeyance until the Money Market has assumed a more favourable aspect. Vigorous efforts will be made to carry out the important line between India and the Australian Colonies, for which purpose a company is formed, upon the direction of which are to be found the names of the most influential merchants connected with Chinese, Indian, and Australian commerce.

The great question as to the best form of cables for deep-sea purposes will again engage the attention of telegraph engineers, as there still exists a great diversity of opinion upon the subject. We have numerous designs of ropes proposed, some of which were subjected to experimental tests under the direction of the late Telegraph Committee; among the most promising we may mention those planned by De Bergue, Messrs. Glass, Elliot, & Co., Allan, Sinnock, Clark, Wells & Hall, Siemens, Rogers, Silver & Co., Macintosh, Hooper, Duncan, and Wright, each possessing great strength, combined with lightness, flexibility, and smallness of bulk, all of which we intend fully to describe in a future number, together with an account of various experimental tests to which they were subjected under our personal superintendence at the Government works.

TRAIN SIGNALLING.

SOMETIMES we think, as the swift train carries us along, making fifty miles a question of as many minutes—and counting, as we often do, the posts at stated intervals, on which are stretched the wires bearing the familiar, though not less woundrous, waves of electricity—"How could the traffic have been carried on without the telegraph?" And yet for many years it was, although, perhaps, the traffic was not what it now is. What would the London and North-Western Railway *now* be minus its telegraph? We know how great the prejudice was *once* against its introduction upon many lines, whose managers would sooner lose a portion of their traffic now than be without their telegraph. If you ask—Why? we say, look at its *convenience*. Suppose a train is late, you, by the telegraph, obtain the reason of delay—anxiety is thus removed; or, if an accident has been the cause, the telegraph is used to send relief. Your luggage, perhaps, is left behind; instinctively you hasten to the telegraph, and by its aid you get your luggage by the following train. Who that has travelled much by rail can fail to know the uses and *convenience* of the "Railway Telegraph?" Perhaps we may stretch the word "convenience," and say the telegraph is *needed* on a railway; but here must end our epithets. We know it *has been* done without; and even now there are existing lines—the Blythe and Tyne for instance—still without their telegraph.

But now we wish to say a word on *safety*—not convenience. We feel our ground is very firm, our latitude extremely broad, when once we speak of "safety;" the whole community will back us up, and those who travel frequently by rail—no very small proportion of our population we opine—will give us thanks for sharpening a weapon for their benefit.

Signalling trains along the line by telegraph from station to station, or, when these are wide apart, from point to point, at intervals best suited to the traffic,—this is an element of safety to the traveller which, we assert, no line should be without. "Convenience" is not the word we would apply to it, because it is rather more than "*in*convenient" to be smashed. We hold it a duty paramount upon our railway men, who night and

day incessantly hold the lives of hundreds in their custody, to give their *first* attention to the *safety* of these lives; and when the traffic on our lines is such that often not two miles of railway intervenes between the trains, does not our unassisted common sense suggest that, if we keep these trains apart, if only separated by a mile of ground, one element—a most important one—of danger is removed? We know that trains may leave the rail, and thus cause loss of life, and clearly it is not the telegraph to which we must resort for aid against *this* peril; but when our "goods" and passengers are jumbled up, a fast train often following behind a slow one, what else can save an accident if it be not the rule to keep a given space between each train perfectly clear? The telegraph alone will aid us in this case; and the plain fact that on our crowded lines some scheme for "spacing" out the road is usually adopted now, the plans, as numerous as the lines, has induced us thus to call attention to the system as a whole, and soon we hope to give our readers details of the plans adopted, pointing out their merits and defects, and hope thereby to stimulate inventive brains to the production of a better contrivance than any tried as yet.

We think the subject one of such importance that Government itself should take it up, and issue a commission to determine which is the system that comes nearest to perfection, and offer rewards for some improvement.

OCEANIC TELEGRAPHY.

By Dr. G. C. WALLICH, F.L.S.

(*Continued from p.* 41.)

It would occupy too much space were we to enter into the whole of the facts bearing on the muddy deposits, with whose presence, over a considerable area of the sea-bed, the sounding-machine has made us acquainted. But there is one point to which we must invite attention, inasmuch as its importance can hardly be over-estimated; and yet, strange to say, it has heretofore been almost entirely overlooked.

In some of the deeper soundings, both on the North and Mid-Atlantic routes, fragments of rock have been brought up. How is the occurrence of these to be accounted for, and what does it betoken? The question is an intricate one, and, so far as our present information goes, does not seem to admit of a perfectly satisfactory solution. This much may be said, however, that their presence on the immediate surface layer of the sea-bed is only reconcilable with one or other of the following suppositions:—They must either have been recently dropped by some means from the superincumbent waters, have been deposited by floating ice during past periods of the earth's history, must occur in beds which were once exposed above the surface of the sea, or be drifting about the bottom through the action of currents.

Now, in no case hitherto recorded have these stones been of large size—probably not larger than a hazel nut—but they present undoubted traces of attrition. Fish, as is well known, sometimes swallow small stones, and, as a matter of course, get rid of them in time; but this would not meet the requirements of the first of the above suppositions, inasmuch as it is obviously improbable that so many fish with stones in their stomachs should be moving about the ocean as would be necessary to account for the fact; and it is still more improbable, if not absolutely impossible, that fish could have conveyed such substances from the distant shores, where they are alone obtainable. So that, viewing this circumstance in conjunction with the fact that no floating ice now-a-days traverses the areas referred to, it is quite certain that the matter is inexplicable on the first supposition.

If deposited from floating ice during past periods of the earth's history, (according to the second supposition, which is by no means impossible,) it follows as an inevitable consequence that the muddy deposits are local in character, and that certain areas of the sea-bed consist of bare rock; or that they are swept away by currents as fast as they are produced. We regard the first of these two views as most conformable with the evidence; for, although there is reason to believe that deep-seated currents prevail with sufficient force in some of the shallower tracts of the Atlantic to move the fine particles of which these deposits are for the most part composed, there is no ground whatever for supposing that they are ever powerful enough to sweep along large objects, such as the stones of which we have been speaking. It will be seen, therefore, that we are fully justified in laying stress on the possibility that extensive areas of exposed rock may occur along the basin of the Atlantic, which have hitherto escaped detection. The third and fourth suppositions are thus disposed of likewise.

But the facts just set forth involve another very important consideration, which, as supporters of no particular creed, we deem it necessary to notice. In assuring ourselves of the absence of currents as a source of danger in Oceanic Telegraphy, we no doubt gain a material point. But to some extent the gain is counterbalanced, and in this wise. Assuming that the bed of the present ocean has been subject, at some antecedent period of the world's history, to the denuding action of atmospheric and terrestrial influences, and has thus been impressed with characters similar to those we see around us on dry land (and that it has been so there is no valid reason to doubt), whatever asperities may have marked its surface when it was first submerged, must remain stamped upon it up to the present time. The denuding action of water in a state of motion is very great; but that of water in a state of comparative quiescence, such as prevails along the sea-bed, must be extremely limited, if it operates at all. Atmospheric agencies, which wear away the rugged features of one district on land and reproduce them on another, are powerless either for good or for evil at the sea-bed. And hence it is certain that, however much the muddy deposits may be constantly contributing towards the toning down of the minor inequalities, they can exercise very little effect as regards those more extensive alternations of level, the absence of which along the sea has been assumed solely because the means heretofore adopted have been inadequate for their detection.

But let us now turn to the living tenants of these deep abysses. It has already been stated that, although the evidence of the vitality of the minute shell-covered creatures obtained in the course of the earlier soundings was altogether inconclusive, more recent observations have established the fact that the conditions prevailing at extreme depths are not incompatible with the maintenance of animal life. The observations in question were made at the close of 1860, during the survey of the North Atlantic route by H.M.S. *Bulldog*. Into the details of these it would be out of place to enter at present; but the proofs they involve may be stated in a very few words.

Thirteen living star-fishes, differing in no important particular from a species common on our own and most northern coasts, were brought up from a depth of 1,260 fathoms, or very nearly a mile and a half, at a point midway between the southern extremity of Greenland and Rockall, and 250 miles distant from the nearest land. These star-fishes, however, cannot be said to have been captured by the sounding-machine, for they came up adhering by their spine-covered arms to the last 50 fathoms of the sounding line, not as voluntary exiles from below, but owing to their having coiled themselves around a material from which they found it impossible afterwards to disengage themselves. Now, apart from all other evidence, the facts in connection with this particular sounding were sufficient to indicate that the star-fishes had been raised from the sea-bed itself, and had not grasped the line whilst floating in some stratum of water intermediate between it and the surface. But by a singular piece of good fortune, the question as to their last resting-place admitted of definite determination on evidence that they bore along with them. To comprehend the value of this it is necessary to mention that, by means of a separate observation taken upon the same spot, the bottom was found to consist almost entirely of the minute shell-covered organisms already referred to; and, taking into consideration the fact that many of the shells were completely filled with the gelatinous substance of which their bodies are composed, and, lastly, the fresh appearance of this substance, the probability is very great that they, in common with the star-fishes, had lived and multiplied at the bottom. But the only circumstance which ought to be accepted as direct proof of their vitality—namely, motion after reaching the surface—was wanting; as, indeed, it well might be, since the passage through the vertical mile and a half of water occupied nearly an hour, and the change of conditions to which the creatures became subjected during that period must necessarily have been very great. Nevertheless, the chain of circumstantial evidence was rendered complete, for, on examining the stomachs of the star-fishes, they were found to contain the minute shelled creatures in abundance: thus clearly

establishing the fact of the star-fishes having attached themselves to the sounding-line whilst it rested on the bottom, and adding the strongest confirmation to the view that the minute creatures referred to were brought up from their natural habitation.

But it was not to be expected that a fact so subversive of all preconceived notions regarding the conditions essential to the presence of animal life on the ocean would be received without the usual amount of salutary scepticism. And hence, on its being boldly announced, not only that highly-organised animals had been brought up from so vast a depth, but that they actually arrived at the surface in a living state, scientific men shrugged their shoulders, and demanded the production of the most complete proofs. These proofs we submit have been produced, and they serve to show that, instead of organic life being carried on in defiance of the conditions so erroneously held to be incompatible with it, the presence of some of these conditions is indispensable to its continuance. In order, however, to render intelligible the doubts that were expressed on the subject, and the precise bearing of the evidence brought forward with a view to dispel them, it is necessary to draw attention to the conditions on which the determination of the question depends.

According to the generally accepted opinion regarding the geographical distribution and vertical limits of marine animal life, the presence of one set of conditions is essential, that of another incompatible with it. Thus we are told that a certain amount of aëration of the water, especially with reference to the quantity of oxygen gas contained in a given volume, and the previous existence of vegetable life in some shape or other, are indispensable to the maintenance of animal life; whereas the increase of pressure beyond a certain degree, and the total absence of light, determine the limit in depth beneath which, it was contended, no living being could exist.

Now, although in the present state of our knowledge, it is difficult to conceive that any animal, no matter how low in the scale, can live in default of a supply of oxygen, we are by no means called upon to believe that this gas is in reality absent in sea-water at great depths.* From observations conducted many years ago by an eminent French experimentalist, M. Biot, it would appear that the swimming bladder of fishes contains a larger quantity of nitrogen than oxygen when they happen to have been captured near the surface; and a larger quantity of oxygen than nitrogen when brought up from a depth of a few hundred fathoms. The researches of other observers would also tend to confirm the view that the quantity of oxygen held in solution by sea-water increases rather than diminishes with the depth; and on theoretical grounds, moreover, there is reason to believe that the presence of oxygen is inseparable from the pressure which prevails at great depths.

In the case of creatures belonging to the higher order, as, for example, fish, the conditions that have been laid down are no doubt indispensable. They cannot support life beyond a comparatively moderate depth; and, as a general rule, it may be taken for granted that no living organism, demanding a supply of free air for its sustenance, or whose structure is of such a kind as to be inordinately affected by an increase of the pressure to which it is subject in shallow water, could, by any possibility, survive a single instant after descending lower than a few hundred fathoms. But there is a large class of creatures, inhabiting the ocean at ordinary depths, whose structure is so universally permeable by fluids that, assuming other conditions to be favourable and the transitions from a low to a high degree of pressure to be sufficiently gradual, it is immaterial whether the medium around them be pressed upon by one or by one hundred atmospheres. In the case of these creatures, as in that of a human being living under ordinary atmospheric pressure, it is only essential that the force should operate uniformly both within and without the body. Hence, in so far as mere pressure is concerned, there is no reason why creatures of the class referred to (and star-fishes are amongst the number) should not be able to exist at all depths.

With regard to the previous manifestation of vegetable life which is said to constitute a condition essential to the existence of animals, both terrestrial and marine, it is only desirable to point out that, were this really a law of nature, it would at once negative the assumption that animal life can be maintained at extreme depths; for, if vegetable products are indispensable for the nutrition of the animal, and no vegetable structures are capable of living in default of a certain amount of light, inasmuch as no light can possibly penetrate to the profounder abysses of the ocean, animal existence must of course be rendered impossible.

But whilst recent explorations of the sea-bed have indubitably indicated that animals can live at those vast depths, they would also seem to show that vegetable life, in any form at least in which we have heretofore detected it, is not co-existent; for whensoever vegetable structures have been found amongst the organic or inorganic matter of the deposits, the peculiar condition of their soft parts has invariably been such as to indicate their having lived in shallower zones, and only descended to the bottom on life becoming extinct. It is manifest, therefore, that the law referred to, however stringently it may apply to terrestrial life, admits of exceptions in the case of marine forms. How these exceptions are provided against remains yet to be ascertained.

But, it may be asked, what are these mysterious little atoms of which so much has been said, and which play so important a part, not only in the composition of the present sea-bed, but of vast tracts of existing dry land.

The animal, as already stated, is one of the lowest in the scale of creation. It consists of a minute particle of viscid matter, not unlike the fluid but yet granular portions of honey both as to consistence and colour, and, like honey, devoid of organization. Nevertheless, it possesses vital contractility, and the power of altering its shape to any extent. The little mass is not naked, however, but, in virtue of another vital faculty inherent in it, is able to extract calcareous matter from the water in which it lives, and re-secrete it in the form of the exquisite shells known to naturalists under the name of *Foraminifera*. In the deep-sea species, to which we are particularly referring, the shells consist generally of a number of chambers ranged in more or less symmetrical order, and each communicating with the rest and with the outer world by one large aperture, and a number of minute pores studded over the entire surface. Through these the little animal is continually projecting, and as continually retracting, delicate thread-like feelers, composed of the same substance as the rest of the body. By means of these feelers it performs the movements of which it is capable, and, in all probability, is enabled to provide itself with food. Hence it will be understood why it was stated in a former portion of these observations, that in the absence of these movements it becomes almost impossible to determine whether the object before us is alive or dead.

But although this wonderful little creature demands special notice, owing to the share it takes in the composition of the deep-sea deposits, numberless other forms are to be met with, equally simple in their nature, but still more beautiful in their structure. And this leads us, in the last place, to inquire whether or not there is reason to apprehend danger from their attacks upon a submerged telegraph cable.

On this point we can speak with confidence. If there be any source through which the abrasion of a cable, either by contact with other substances, or the attacks of creatures able to bore into its coverings, and thus destroy or impair its insulation, may be obviated, it is through the gradual incrustation that these humble shell-builders are sure to form around it. Accordingly, it becomes of the utmost importance to select, as far as is practicable, those areas of the sea-bed which are covered by the foraminiferous deposits, and to avoid those which are bare. Minute Annelids unquestionably exist even at the greatest depths, and amongst these there are some capable of doing mischief. That they can penetrate gutta-percha solely by means of the boring organs with which they are provided, we altogether disbelieve. But, in most cases, there is ground for suspecting that their penetrative powers are materially aided by secretions capable of acting chemically on the substances attacked. Of the nature of the secretion, or its possible effect on caoutchouc or gutta-percha, we know nothing. But this is no reason for repudiating the possibility of an event, which if brought about only once in the 2,000 miles of cable, would prove fatal to its working integrity. It only remains to be added, that we are no alarmists. We would neither conjure up, magnify, nor ignore danger. What we desire and believe to be indispensable, if telegraphic communication across the Atlantic is to be viewed in any other light than as a source of national chagrin, is that measures should be forthwith adopted to add to the scanty information we already possess regarding the sea-bed; under the firm conviction that whatever difficulties may present themselves, they require only to be understood to ensure their being surmounted.

* M. Pasteur, the French chemist, in his recent experiments on Ferments, has sought to show that some of the so-called Infusoria are able to exist without oxygen.

TO ERECT A LINE OF TELEGRAPH.

(*Continued from p.* 29.)

As three different lengths have been given for the arms or cross pieces, viz., 18, 19, and 22 inches, it is necessary to explain that the reason of this is to prevent the wires coming into contact when an accident occurs, by which one of them breaks away from the insulator that supports it.

The longest arm should be fixed nearest the top of the pole; then (12 inches lower down) the 20-inch arm, and finally the 18-inch arm. If the wire comes away from the top arm, there is then no fear of its coming in contact with those on the lower arms, unless it be very slack, in which case the wind may drive it occasionally against the nearest wire, and thus an intermittent contact would arise.

This article has been forestalled in last week's number of the Journal as to the method of fixing the wires used for lightning-conductors (see p. 43); but the writer might have added a word of caution, that when painting the poles care must be taken not to leave the earth-wires covered up. A wise precaution is to take a knife and scrape the conductors after the poles have been painted. The wires themselves, when first fixed, should project four inches at the top of the pole, above the cap, and be twisted twice round the butt before the pole is set. In notching the poles to receive the arms, do not fix them all on one side, but alternately, so as to preserve an equilibrium of weight upon the pole. Being solicited to give a list of tools required, and the cost of such as are necessary to erect a line of telegraph, the following will, it is trusted, be found useful and correct:—

Lined bass, each	£0	4	0
Draw vice and tongs, per pair	0	17	6
12-inch spanner, each	0	12	6
Drawing tongs, per pair	0	5	0
Monkey wrench	0	7	0
Half dozen 3-square files, selected	0	7	0
Hand-saw	0	3	0
Tenon-saw	0	3	6
One pair 7-inch pliers	0	3	6
One pair 5-inch ditto, solid	0	3	0
One pair long-nosed pliers	0	2	0
One soldering-iron	0	4	0
One wood mallet	0	1	0
Two chisels, 1s. each	0	2	0
Two screwdrivers, 1s. 6d. and 2s. each	0	3	6
One large hammer	0	3	0
One small ditto	0	2	0
One plane	0	4	0
Two augurs, 1s. 4d. and 1s. 6d. each	0	2	10
Two gimblets, 4d. and 6d. each	0	0	10
One drawing-knife	0	2	0
One shave	0	1	6
Two squares, 2s. and 3s. 6d. each	0	5	6
One pick	0	4	0
One spade or tool	0	2	0
Two tar-pots, 4s. and 5s. 6d. each	0	9	6
Two brushes, 1s. 3d. and 1s. 9d. each	0	3	0
One fire-pot	0	3	6
One spirit-lamp	0	2	6
Pair blocks and fall	1	2	0

Of the above a lineman will require a complete kit, the labourers only wanting picks and spades. Surely for a regular employment, such as that of a telegraph lineman should be, the investment of £7 6s. 8d. as his stock in trade is not more than it is right to expect.

So far, then, for the construction of overground lines, and it is assumed that the remarks apply equally to works on railways or highways. In every case be particular to leave the ways clear, and do not consider that your work is finished if the ground is not well filled in and levelled; and if any subterranean work has been carried out requiring paving or macadamizing, consult with the Board surveyor whom to employ to set all straight. Ten to one he will do it himself; but the expense will be less than if you select a man of your own choice, however good he may be, in which case you will find a bill following you for doing it twice over "to the satisfaction of the overseers." A fair charge for setting a road in order is 6d. per square yard.

For simply raising stones, opening a trench two feet deep, filling in and setting (exclusive of the above charge), 10d. per yard run is a fair estimate. It will cost this to do it, and matters little if you employ a contractor or do it with your own men.

In underground work remember Mr. Varley's dictum: gutta-percha will remain unchanged for months *in air* if the light is excluded, and *for years* in water if coated with Stockholm tar. A good plan to adopt, therefore, to preserve your gutta-percha-covered wires is to dig a trench two feet deep,—this will be sufficient to be out of the way of frost,—place in it some wooden boxing rather larger than your cable of wires requires. The boxing may be rough cut and not planed; the rougher the better, as the tar and pitch will creep into it. An ordinary square groove will answer, or it may be V shaped. Prepare your wires by a double covering of tarred yarn, and when laid in the boxing pour into it warm tar, with sufficient pitch mixed in it to allow it to become solid as quickly as it becomes cold. Before it gets hard, and while running over the sides of the boxes, tie on the lids—plain, flat, rough pieces of scantling—and, finally, with a tar-brush give the whole outside a thick coat of tar. While this is warm, fill in your trench, and the earth will cling to the boxing on all sides, excluding air, and making the job as complete as possible. There need be no fear of rapid decay of gutta-percha if this plan is adopted. Lines so laid eight years ago are as good as when the trench was first filled in; and as affecting the question of maintenance it is most important.

To pursue this question efficiently we shall next prepare a summary of The General Telegraph Act, and append the forms of notice required to be given in compliance with the same.

THE INTERNATIONAL EXHIBITION, 1862.

(*Continued from p.* 42.)

W. T. Henley, H.M. (United Kingdom, 2,908), exhibits specimens of cables covered and laid by him. They are entirely similar in general construction to those already described, and have been for the most part successful. A list of these cables is contained in Table B.

TABLE B.—CABLES LAID BY MR. HENLEY.—OCTOBER, 1862.

Date when laid.	WHERE LAID.	Number of Conductors.	Length of Cables in Statute Miles.	Lengths of Insulated Wire in Statute Miles.	Period of Working.
1857	Ceylon to Mainland of India	1	30	30	5 years.
1859	Spain to Africa	1	25	25	Not known.*
1859	South Australia to Tasmania	1	240	240	†2½ years.
1860	Denmark, across Great Belt	6	14	84	2 "
1860	Denmark, across Great Belt	3	14	42	2 "
1860	In Arracan	1	116	116	2 "
1860	Barcelona to Mahon	1	198	198	2 "
1860	Minorca to Majorca	2	35	70	2 "
1860	Iviza to Majorca	2	74	148	2 "
1860	St. Antonio to Iviza	2	76	152	2 "
1860	Across rivers in Egypt	3	6	18	2 "
1861‡	Beachy Head to Dieppe	6	80	320	4 wires good.
1862§	Across an arm of Cork harbour	11	—	0·625	7 months.
1862§	Across Blackwater River, Ireland	4	—	1·75	6 "
Number of miles of cable and insulated wire laid			908	1,445	
Deduct out of working order			125	125	
Number of miles of cable and insulated wire in working order			783	1,320	

The following tables give the details of the principal cables hitherto laid by all makers. It is divided into three heads: 1st. Those which have been wholly successful, and are now working (October, 1862); 2nd. Those which may be said to have been partly successful, inasmuch as they worked for some time; 3rd. Those which wholly failed, or, in other words, never worked at all. The writer has added in each case what he considers the probable cause of the total or partial failure. The dimensions of the wires, &c., have been given in the Birmingham wire gauge, because measurements in decimals of an inch would have given a fallacious idea of the accuracy of the data. It is well known that in practice the same number does not always mean exactly the same size. A short table is added giving the strict value of the gauges in decimals of an inch.

* Old Atlantic. † One hundred miles out of working order.
‡ Manufactured in 1853 by Messrs. Glass, Elliot, & Co., but laid by Mr. Henley.
§ Silver & Co.'s india-rubber.

TABLE C.—LIST OF SUBMARINE CABLES HITHERTO LAID.

PART I.—*Cables which are now at Work.*—October, 1862.

No.	Date when laid.	From	To	Conductors. No.	Conductors. Size per B.W.G.	Size of Insulator per B.W.G.	Outside Wires. No.	Outside Wires. Size.	Length of Cable in Statute Miles.	Length of Insulated Wire in Statute Miles.	Maximum depth of Water in Fathoms.	Weight in Tons per Statute Mile.	Length of time the Cables have worked.	Remarks.
													Years.	
1	1851	Dover	Calais	4 wires.	16	2	10	1	27	108	30	6	11	The first iron-covered cable.
2	1852	Keyhaven	Hurst Castle	4 do.	16	7	—	16	3	12	—	—	10	The first application of pure india-rubber to submarine cables. The outside covering was made of wires plaited together.
3	1853	Denmark	Across the Belt	3 do.	18	4	9	2	18	54	15	4	9	
4	1853	Dover	Ostend	6 do.	16	2	12	2	80½	483	30	5¾	9	
5	1853	Frith of Forth	— —	4 do.	16	1	10	8	5	20	—	7	9	Four cables, galvanised, and twisted together.
6	1853	Portpatrick	Donaghadee	6 do.	16	2	12	2	25	150	160	6	9	
7	1853	England	Holland	1 wire.	16	1	10	8	120	120	30	1¾	9	One of four similar cables laid in 1853-1855. They were found too weak, and, after having been repeatedly broken and repaired, three of the four have been lifted and replaced by a very heavy cable, No. 20 in list, part I. The gutta-percha was covered with tape saturated with Stockholm tar. Copper 63 lbs. per mile.
8	1854	Portpatrick	Whitehead	6 wires.	16	2	12	galvanised 2	27	162	150	6	8	
9	1854	Sweden	Denmark	3 do.	16	2	10	2	12	24	14	6	8	One wire of this cable is out of working order.
10	1854	Italy	Corsica	6 do.	16	1	12	1	110	660	325	7½ to 8	8	These cables have never cost anything for repairs; they are similar to the cable intended to connect Sardinia and Africa, No. 5 in list of failures, part III. They are also similar to No. 48, part I., and manufactured at the same time.
11	1854	Corsica	Sardinia	6 do.	16	1	12	1	10	60	20	7½ to 8	8	
12	1855	Egypt	— —	4 do.	16	2	10	1	10	40	—	5¼	7

50	1862	England	Holland	4 wires.	13	0	10	00	130	520	30	9	2	The shore ends of this cable were covered with hemp and bitumen. They weighed 15½ tons per mile.
51	1862	Across rivers in Ireland	—	—	—	—	—	—	—	1½	—	—	7	Two short pieces of cable, the conductors of which are insulated with india-rubber.
			Totals						5345½	9456½	These totals can only be taken as approximations, as the exact length of several of the cables is not known to the writer.			

* Since writing the above this cable has failed—temporarily at least.

(*To be continued.*)

TELEGRAPHY A PROFESSION.

The periodical announcement of lucrative appointments at the disposal of the Under-Secretary of State for India, on the electric telegraph staff of that country, naturally incites our young men to profitable study, and encourages that healthy spirit of emulation so essential in those who seek advancement. In the month of May next, the competitive examinations will be commenced in London, for twenty-five appointments, of a monthly money value, varying from 3,000 rupees to 150 rupees; and, judging from the number of communications we have received on this subject, we conclude that there will be a large number of candidates, and an animated competition. The conditions of appointment have been previously published in this journal. Arbitrary, yea, absurd as are some of the requirements, considered in their bearing upon the occupation to be engaged in by successful candidates, there will be found many who are prepared to "try" every subject set by the examiners.

It becomes necessary, therefore, for those of our readers who contemplate entering the arena, to fortify themselves, by every possible means, for the crucial tests to which they will be subjected. To those who have the means at their disposal, we would recommend a careful preparation, by a practical electrician, prior to examination. We do not urge this course as essential to success, or we should discourage that large class of plodding, self-instructed students, to whom the world of science has been, and ever will be, so much indebted; but we advise a special course of instruction wherever the educational qualification exists, without the experimental knowledge so necessary in the business of a telegraph engineer.

In our advertising columns will be found an announcement from a practical telegraphist, who conceives that a fitting opportunity now presents itself for the professional preceptor to introduce himself to public favour; and in this view we heartily concur. Architecture and engineering have long been honourable professions, success in either of which has only been attained by application and study under the most experienced masters. The science of electricity, in its practical applications, is but imperfectly understood, and we are anxious to see the best method adopted whereby its development may be ensured, and a school of telegraphy established, which shall adorn the birth-place of the art.

A new sphere has been opened up, wherein the experienced electrician may turn his practice to profitable account. Mr. Dodwell has initiated a course which is calculated to greatly exalt telegraphic science, and to assist those who may be desirous of attaining to proficiency in a profession which is becoming more important as nations advance in civilization.

WHO IS MR. REUTER?

All the world is asking this question. Is the mysterious individual who tells us through the public press what battles have been won or lost—what kings have decamped, or what words emperors have spoken an hour since in far-off countries, which will shake the political world to its foundation—is this Mr. Reuter an institution or a myth? Must we count his name like one of those which have an existence in the heathen mythology only, or is he a man like ourselves, having "feelings, organs, dimensions," &c.? If he be, by what extraordinary organisation does he manage to gather up over night a summary of events over the entire continent, and to place it before us as a startling interlude between coffee and toast at the breakfast table? Nay, how is it that through his mouth, if we may so term it, we hear for the first time of a successful battle in China, or of the madness of the Southern slave states of America? To answer all these questions is the purpose of the present paper, and we may claim for this journal the privilege of being the first to satisfy the public inquiries relative to this very interesting subject. That Mr. Reuter, omniscient as he may appear to be, shares our common humanity. His history is like that of all courageous and energetic men, who, seizing upon a new idea, work it persistently and silently, until one fine morning, from comparative obscurity they suddenly find their names famous.

The practical success of the first working telegraph on the continent—that between Berlin and Aix-la-Chapelle in 1849—convinced Mr. Reuter, in common with every thinking man on the continent, that a new era in correspondence had arisen, and he determined to avail himself of its facilities for the public advantage. The first office for the furtherance of telegraphic communication was opened at Aix-la-Chapelle, an admirable spot, lying so conveniently between the east and west of Europe. This office formed the first centre of that organisation which has since gathered up into the hands of one man for all general and public purposes the scattered electric wires of the world. In order to correct breaks in the most direct line of transmitting news he had to supplement the wire with contrivances of his own, so as to insure priority of information. Thus, the better to gain time in the journey between Aix-la-Chapelle and Brussels, he employed a service of carrier-pigeons. By this means on this distance alone he was enabled to anticipate the mail train between the two places by six or eight hours. In order to ensure regularity and safeness in transmission, each message was despatched by three different pigeons, which made the passage from Brussels to Aix-la-Chapelle in an average period of one hour. When the telegraphic line was extended from Aix-la-Chapelle to Quievrain, on the Belgio-French frontier, and the French Government extended their line from Paris to Valenciennes, there remained a gap of only five miles in the line of telegraph between the French and Prussian capitals, but insignificant as this space was, the delay thereby occasioned was enormous. To obviate this, relays of saddled horses were always kept in readiness to forward despatches between the two points.

As line after line was opened in succession, each was made subservient to his system, and when the cable between Calais and Dover was successfully laid in 1851, Mr. Reuter, who had become a naturalised subject of Her Majesty, transferred his office to London, which thenceforth was put in connection with the principal continental cities. Up to this time Mr. Reuter confined his attention to the conveyance of commercial despatches, but it now struck him that the time was arrived for making the telegraph the handmaid of the press. One of the distinguishing characteristics of the British press is the vast expense to which it goes for obtaining exclusive intelligence. The principal morning papers were in the habit, at this time, of running expresses at an enormous cost. The *Times*, for instance, possessed a fast steamer, which conveyed to England news from Calais the moment it arrived from Paris. M. Reuter offered to supply the obvious want; but without success. The obstacles presented by the existing system were not yet to be overcome; and besides, a certain prejudice had been excited against political telegrams in consequence of the errors they so often contained. Sometimes they had to be translated into three or four languages before they reached the British public, and errors were but too likely to creep in under such circumstances. A second time, too, he was equally unsuccessful.

Mr. Reuter did not lose heart, however, as he foresaw that the days of daily political telegrams were near at hand. "All good things are three," says the German proverb, and for a third time, in 1858, Mr. Reuter made his offer to the press. This time, however, he sent his telegrams for one whole month to all the editors in London, leaving it to their option whether they used them or not. The quickness with which Mr. Reuter received his telegrams, and the accuracy of the information they contained, were soon appreciated, and one newspaper after another became subscribers. His telegrams did not attract particular notice, simply because no great public event gave him an opportunity of showing the value of his system. So matters went on until the 9th of February, 1859. On that day the Emperor made his famous speech, in which he threatened Austria through her ambassador. His ominous words were uttered at one P.M. in the Tuilleries, and at two P.M. the speech was published in a third edition of the *Times*, and had shaken the Stock Exchange to its foundation. This was a dramatic hit, and thenceforward every one looked out for Mr. Reuter's telegrams. The war in Italy followed, and, in order to receive authentic accounts from all quarters, Mr. Reuter sent special correspondents to the French, Austrian, and Sardinian camps; and on one occasion it happened that he published three different telegrams of the same battle from his correspondents in the different armies. Many of these telegrams were, from their very nature, short; but on occasions, important speeches, parliamentary debates, and other political intelligence of especially English interest were telegraphed *in extenso*. The adoption by the English press o[f] the few short but decisive facts communicated by the telegraph did n[ot], however, do away with the "exclusive special correspondents" o[f] the chief morning papers; on the contrary, it allowed them mo[re] time to elaborate their information, and to go into detail. A do[zen] lines gave us the fact of the victory at Solferino; but the battle itself a

week afterwards stood before the British public with all the photographic strength and completeness of the *Times*' special correspondent's pen.

The impartiality and accuracy by which Mr. Reuter's telegrams were characterised, succeeded in procuring him the confidence of the press. The newspapers of the chief provincial towns were not long in availing themselves of his system, which ended in depriving the metropolis of the monopoly of early intelligence. The daily papers of the great towns of the north of England and of Ireland possess exactly the same early telegrams as the London daily papers, by means of Mr. Reuter's system, which posts England as well up in the news of the world, at her furthest extremities, as she is in the metropolis itself.

News from England is, in the like manner, conveyed by Mr. Reuter to all the chief continental cities. Thus the people of St. Petersburg may read every morning abstracts of the previous night's debate in the British Houses of Parliament.

What Mr. Reuter has already done for Europe he is about to do for the other quarters of the globe. It will have been observed that all our earliest information from America, India, and China, the Cape, and even Australia, is derived from this gentleman's telegrams. In all these countries he has located agents, who transmit him news in anticipation of the mails. There being no direct telegraphic communication between England and those countries, Mr. Reuter avails himself of every telegraphic line *en route*. Messages from America, for instance, are telegraphed up to the latest moment to the last port in the Atlantic where the steamer touches; they are then landed either at Queenstown, Londonderry, Galway, Liverpool, or Southampton, whence they are telegraphed to London. News from the East is received in an accelerated manner by a similar method. All the telegrams first come into the hands of Mr. Reuter, whose day offices are near the Exchange, and whose night offices are in Finsbury-square; thus this gentleman is, without doubt, as regards the affairs of the world, the best informed man in it. He gives his political telegrams to the press alone, and never allows them on any account to be communicated beforehand to merchants and bankers for the purpose of speculation.

In order to make the separation between the political and commercial departments of his establishment the more complete, he has removed the former to Waterloo-place, at the West-end, whilst the latter remains at the City offices. These offices are open day and night—the day staff of clerks working from ten A.M. till six P.M., and the night staff—a far more numerous one, in consequence of the far longer hours of work—being engaged in relays from six P.M. one evening till ten A.M. next day. All the offices are connected together by the electric wire, and to still further facilitate the transmission of telegrams to the different newspapers, the wires are being continued from the West-end office right into the editor's room of each journal, who, by means of Wheatstone's universal telegraphic apparatus (a description of which we shall give in an early number of this journal), is enabled to read off his own messages instead of receiving them, as heretofore, by messenger. The pedestrian, as he walks along Fleet-street and the Strand, will perceive high over head what might be termed the political spinal cord of the metropolis; every here and there it gives off right and left fine filaments; these are going to the *Globe*, the *Sun*, the *Morning Post*, the *Herald*, the *Standard*, the *Telegraph*, and all the other daily papers which line this great thoroughfare. These are the lines by which Mr. Reuter puts the whole British public in possession of the thoughts, and records the actions of the rest of the world; and as we watch the wires ruling their sharp outlines against the sky, for all we know they are conveying words which may affect the destinies of millions yet unborn.—*Once a Week.*

REPORT OF THE DIRECTORS OF THE MEDITERRANEAN EXTENSION TELEGRAPH COMPANY (LIMITED).

THE Balance Sheet for the half-year just ended shows the Company to be in a better position at present than it has been since its commencement.

The improvement in the revenue has been considerable, and, but for the interruption which occurred in the Malta and Alexandria line in the early part of the half-year, there is little doubt that the receipts would have been nearly doubled as compared with the previous half-year.

An interruption has just occurred on the same line again, but from the circumstances with which it is connected, there is little doubt it will be repaired almost immediately, as the lessees of the line entertain no doubt respecting the result.

The Directors regret to announce the decease of Mr. J. W. Brett, one of your Board, which occurred during the past half-year. They have endeavoured to repair the loss which the Company has sustained in his death, by electing, in conformity with the "Articles of Association," Captain A. T. Hamilton, who was formerly a director; and whose valuable services, they feel assured, will conduce to the interests of the Company.

The Company's cables continue in good working order.

The Directors recommend the usual dividend—8 per cent. per annum—on the Preference Shares; and 4s. per share—equal to 4 per cent. per annum—on the Original Capital.

They also recommend the usual addition of 10 per cent. on the gross earnings to the Reserve Fund.

HENRY MOOR, Chairman.
HENRY C. ORTON, Secretary.

158, Gresham House,
22nd January, 1864.

Deduct Alexandrian Lessees' proportion of Rent of Malta Offices		23 19 9
		£1,992 9 3

[It will be seen from the following report that, notwithstanding the precautions which were observed in the manufacture and submergence of the Malta and Alexandria cable, an interruption of the communication, extending over a period of two months, occurred last year. Advices, contemporary with the publication of the accounts, announce that the line is again faulty. A vessel has already been dispatched with an efficient staff, and fitted with apparatus for raising and making good the damage, and we trust that the anticipations of the directors with reference to its restoration may be realised.]

REPORT OF THE DIRECTORS TO THE PROPRIETORS OF THE TELEGRAPH TO INDIA COMPANY, LIMITED.

IN presenting their Report to the Shareholders, the Directors have the satisfaction of stating that the remaining Assets have now been disposed of, as will be seen by the accompanying Statement of Accounts, and that there are no further liabilities.

Messrs. Glass, Elliot, & Co., the lessees of the line, have intimated that they will make no deduction from the half-yearly payment of £1,250 for the period ending 31st December, 1863, although the through communication was interrupted for about two months; they reserve to themselves, however, the right to claim the amount (£200) at any future time, should they think fit.

The Directors recommend that a dividend, at the rate of 5 per cent. per annum, free of Income Tax, be paid to the Shareholders for the half-year ending 31st December, 1863, payable on and after the 15th instant.

The Directors regret to inform the Shareholders that intelligence has been received of a further interruption on the Malta and Alexandria cable, but they understand from Messrs. Glass, Elliot, & Co., that a ship has been despatched with a proper staff to repair the fault, and that the communication will, in all probability, be restored in about a month from this time.

During the interruption on the Malta cable, this Company will get the benefit of the receipts on the Alexandria, Cairo, and Suez line; and in consequence of the recent increase of the local traffic, the Directors do not anticipate that there will be any deduction from the dividend of 5 per cent. per annum during the remainder of the lease.

Before that term shall have expired it is confidently expected that there will be a further extension of the Telegraph in the direction of Aden, and possibly of India, by which the Company's property will be greatly enhanced in value, and the Directors will be able either to dispose of the line, or to work it themselves, with advantage and profit.

The Directors have to lament the death of one of their colleagues, Mr. Alexander Wilson, since the last meeting of the Shareholders. Under the existing circumstances of the Company, it is suggested that his seat at the Board should not at present be filled up.

In compliance with the requirements of the Act of Parliament, the following Directors retire by rotation, and, being eligible, offer themselves for re-election:—Philip Patton Blyth, Esq., Frederick C. Gaussen, Esq., and John Farley Leith, Esq.

The auditors, J. A. Franklin, Esq., and A. S. Wildy, Esq., also retire, and offer themselves for re-election.

WILLIAM DENT, Director.
WILLIAM MAYO, Secretary.

MATERIALITY OF THE ELECTRIC FLUID.—Mr. Lake, of the Royal Laboratory, Portsmouth, communicated to the *Lancet* a few years ago the results of a singular experiment, which appears to show that the electric agent is really fluid; and that when collected so as not to exert its powers of attraction and repulsion, it obeys the laws of gravitation like carbonic acid and other gases. The electric fluid was received in a Leyden jar insulated on a glass plate. At the lower part of the jar was a crack in the side, of a star-like form, and from around this the metallic coating was removed. On charging the jar, it was observed that the electric fluid soon began to flow out in a stream from the lower opening; and on continuing the working of the machine, it flowed over the lip of the jar, descending in a faint luminous conical stream (visible only in the dark) until it reached the level of the outside coating, over which it became gradually diffused, forming, as it were, a frill or collar. When the jar was a little inclined on one side, there was a perceptible difference in the time of its escape over the higher and lower parts of the lip, from the latter of which it began to flow first. On discontinuing the working of the machine, the fluid first ceased to flow at the lip of the jar, and then at the lower aperture. On renewing the operation, it first re-appeared at the lower aperture, and afterwards at the mouth. This very ingenious experiment appears to establish the fact, that the electric fluid is material, and is influenced, under certain circumstances, by the laws of gravitation. We believe that Dr. Laming has made several experiments to the same effect.

CORRESPONDENCE.

THE BONELLI TYPO-ELECTRIC TELEGRAPH.

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—As a telegraphist of some years standing and experience, I was much pleased with the clear and satisfactory reply of Mr. Henry Cook to your correspondent "J. P." I confess that I had an indifferent opinion of M. Bonelli's apparatus as one of practical utility, but Mr. Cook's explanations have modified my views considerably. An apparatus capable of transmitting matter at the rate stated by Mr. Cook would undoubtedly effect a great change in our telegraphic system, and confer a boon on the newspaper interest of the country. I am well acquainted with the powers of the Morse's instrument for transmission, and which are well defined in Mr. Cook's letter; and, perhaps, it is not generally known, that the old double instrument can be employed with greater effect than either Morse's or Bain's in the transmission of long speeches, when manipulated by expert telegraphists.

The great drawback to the adoption of the typo-telegraph of M. Bonelli appears to me the expense of constructing and maintaining a line where five or six wires are necessary for working the instrument. Suppose that one or two of the line wires were broken, could any communication be carried on then?—Yours, &c.,

25 Jan., 1864. D. P. L.

MR. ANDREWS' PNEUMATIC APPARATUS.

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—It is with the liveliest gratification I have seen the publicity given through your columns to the attempt of Mr. France to gain credit for the productions of another's labours. It is not because of any personal feeling *against* Mr. France, or *in favour of* Mr. Andrews, that I say *this is a step in the right direction.* I speak feelingly, as one who has more than once been treated like Mr. Andrews. It would be a grand thing if some law could be made to prevent the appropriation of other men's ideas, and meet the case of those who are not content with this, but must seek to get the credit for them also. The fact is, patents are useless if you cannot defend them; or if you can, another snaps up your idea, if good, adds a screw here and there, a wheel, or perhaps a spring, and trumpets up the thing as his. It is time a stop was put to all this paltry system; and let the first step be to expose those who, lacking may be the wit themselves, seek to grow fat on others.—Your obedient servant, LUX.

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—Amongst the number of your subscribers none have hailed the appearance of your Journal with greater pleasure than myself. It supplies a desideratum long felt; and I am inclined to think that the *Telegraphic Journal* will, in some degree, revolutionize the telegraphic world.

Formerly there has been a striking exclusiveness in connection with telegraphy and its concerns. The public, from the original high rates of telegrams, instinctively avoided a telegraph office, and, surprising to say, manifested little desire or aptness to peep beyond the curtain of facts into the sanctuary of causes. The superficial ideas they obtained created immense astonishment and admiration, but the idea of an inquiry into electrical principles and their application to telegraphing was terrific. The clerks, from the distances which separated them, and want of other means of communion than the wires, were not induced to act combinedly, as for instance, in the formation of societies and clubs, or in meetings for mutual improvement, &c.: the absence of telegraphic journalism prevented the interchange of ideas, the general dissemination of news of a professional character, and the communication of electrical knowledge.

Now, however, the public are becoming better acquainted with the working of telegraphy and with electricity as a science. Lower prices for messages, erections, &c., are attracting them into close relationships with the telegraph. Telegraphists have their improvement societies, their dramatic clubs, their insurance companies, dinners, cricket clubs, &c., and, lastly, we have our journal—the agent for conveying to all quarters news, notions, and science—so that a clerk at a remote station can hear of the affairs of the whole telegraphic world. We have opened to us, in the publication of your Journal, a new phase of existence; a means of communion and concentration of interests.

In reading the manner in which you purpose to subdivide the contents of your paper, I was pleased to see that you apportion a part to all classes; that you do not treat of science to the exclusion of general news, nor of the latter to the exclusion of something for the poor clerks. Your columns are a medium alike to all. For its ultimate success I entertain no doubt, and I hope I am not illogical in supposing that, after a certain maximum of remuneration is received, an increase in circulation will produce a proportionate decrease in price.—I am, Sir, yours, &c.,

Stockton, 21 Jan., 1864. W. H. NETTLETON.

TELEGRAPHIC NEWS.

MR. CYRUS W. FIELD has again arrived in England, being his thirty-first voyage across the Atlantic, to renew his efforts to unite by telegraph the British and American shores. The fidelity of Mr. Field to the great and important undertaking, so long identified with his name, has become proverbial on both sides the Atlantic. We trust that the effort which is to be made next year to lay down the cable will prove successful, as there is every reason to believe that it will be the case.

WE regret to learn that Mr. Statham, so long the manager of the Gutta-percha Company, Wharf-road, City-road, and identified with telegraphic operations, both sea and land, has been suffering for some time from severe illness; and the last information received represents his health to be in a most precarious and dangerous state.

SOME interesting and successful experiments have recently been made between the Liverpool and London stations of the Electric Telegraph Company, with a telegraphic apparatus invented by M. Casselli, and termed the "Pantelegram." M. Casselli has succeeded, by very ingenious mechanism, in more practically carrying out, through the medium of the wires, the principle of transmitting to distant stations *fac simile* copies of messages as written by the sender, and also exact counterparts of designs and portraits. It seems to be expected that the invention will prove a valuable adjunct to the progress of telegraphy.

THE Bonelli Telegraph Company are now erecting, on each side of the Mersey, enormous poles, or masts, for supporting an aerial cable across that river. During the last storm, the poles first erected were completely destroyed, and the operations of the company were temporarily stopped. Some idea of the manner in which the new works at Runcorn are being done, may be gathered from the fact that the new top-masts are as large as the main-masts of the old standards. The new masts are 2 feet 6 inches in diameter at the base, and 136 feet in height.

THE LAST TELEGRAPHIC FEAT.—The transmission of Messrs. Scholefield and Bright's speeches, delivered before a meeting of their constituents, in the Town Hall, Birmingham, on the 26th instant, shows the wonderful capacities of the electric telegraph. The transmission of the speeches commenced at half-past 8 o'clock, P.M. Three instruments were employed—namely, Morse's—put in action by Mr. Varley's relays. After a stoppage of about half an hour, between 11 and 12 o'clock, P.M., the work was proceeded with until half-past 2 o'clock, when the transmission was completed. The matter, as it was received, was despatched to the newspaper offices. The report of the speeches, as it appeared in the *Times*, contained, in round numbers, 49,000 letters, or 12,000 words, occupying six columns. The length of the paper-ribbon upon which the speeches were printed, exceeded one statute mile.

MAGNETIC TELEGRAPH.—The employés of the Magnetic Telegraph Company, with their friends, held their third annual soiree in the Lesser Trades Hall, Glassford-street, Glasgow, on Wednesday evening last. E. Tansley, Esq., District-Superintendent, occupied the chair. Having discussed an excellent tea, the chairman, after expressing the pleasure he felt in presiding on the occasion, gave an outline of the rapid progress which had been made in the science of telegraphy during the last few years, and also referred to the important works on which some of our most eminent electricians are now engaged. The meeting was then entertained with songs and recitations from several talented amateurs, after which, the hall being cleared, dancing was commenced, and kept up till an early hour.

TELEGRAPH LINE BETWEEN GOREY AND ST. HELIER.—This line was completed on Wednesday, the 20th inst., and on Thursday the batteries and instruments were tried on it, and showed it to be in perfect working order. The rate for telegrams between St. Helier and Gorey will only be 6d. The line is erected upon poles for a distance of 4½ miles from Gorey Pier, where the new station is situated, to the corner of the Belvidere-road, in George Town, where the last pole is standing. Here the overground wire is connected with a piece of cable laid underground through the streets for rather more than half-a-mile, and which ends at the principal office in Library-place. The stretches of the wire between the poles are rather longer than is usually the case on overground lines, the average length of the spans being 220 yards. There is one particularly long span near Gorey, the wire being stretched from the top of the Martello Tower on the common to the highest part of the road, a distance of 430 yards. The line of route was laid down by Mr. Gerhardi, the Company's Superintendent for Jersey, and has been executed under his personal superintendence. This day the line was formally opened by the transmission of the following messages from the Superintendent to the Lieut.-Governor:—"To His Excellency Major-General Burke Cuppage, Lieut.-Governor of Jersey.—Gorey, January 23, 1864.—I take the liberty to address to your Excellency this, the first Telegram transmitted by the new Line between St. Helier and Gorey, to inform your Excellency that the line is from this moment open to the public. —C. GERHARDI, Superintendent for the Island of Jersey." The Lieut.-Governor replied as follows:—"His Excellency the Lieut.-Governor congratulates the Submarine Telegraph Company on the accomplishment of an object which must be of so much benefit to the public at large, and thanks them for their communication."

THE directors of the Electric and International Telegraph Company have resolved to recommend to the proprietors, at the general meeting to be held on the 11th of February next, to confirm a dividend of £3 10s. per cent. for the last half-year.

MR. F. JAMES, late a clerk in the employ of the Electric and International Telegraph Company, at Edinburgh, but who was more recently employed in the Government telegraph service at Suez, went across the Creek, on the 14th inst., to spend a day's pleasure with two friends, and while indulging in sports of the field, accidentally shot his left arm off; mortification ensued, which, we regret to announce, proved fatal within twenty-four hours of the accident.

THE Kurachee papers give out a report of the fact that Kurachee had been fixed upon as the head-quarters of the Persian Gulf and Bagdad line of telegraph.

THE *Marian Moore*, which left the Downs on the 17th August, arrived at Bombay on the 27th November. Upon examination of the cable, which had been kept in water-tanks on board, the insulation was found to be higher than it was when it left Woolwich: the fact is a corroboration of well-conducted experiments. All the machinery required for the laying of the cable was in position on board the vessel, and it was expected that the *Marian Moore* would be able to proceed to its destination at once, towed by H.M. steamer *Semiramis*. Lieut.-Col. Stewart, Sir Charles Bright, Dr. Esselbach, and Messrs. Webb and Laws were all well, and everything appeared favourable to success. The *Zenobia* and the *Corromandel*, two fine Government ships, were also appointed to assist in the work.

THE *Cossack*, 20, Captain W. R. Rolland, received orders on the 21st inst. to hold herself in readiness to sail for Tripoli and Benghasi. She is to convey Mr. Saunders, electrician to Messrs. Glass, Elliot, & Co., to these places, for the purpose of examining into the state of the Malta and Alexandria telegraph cable, which has stopped working since the 13th inst. Mr. Saunders was expected from Marseilles on the night of the 22nd inst. A steamer especially fitted for such employment has been ordered from England to the Mediterranean to repair the cable. It has been rumoured, also, during the week, that the Oran and Carthagena cable had met with an accident; we have made enquiries of the contractors, who assured us that they have not received any information confirmatory of the statement.

THE ELECTRIC AND INTERNATIONAL TELEGRAPH COMPANY.—The annual meeting of the chief officers of the North-Western section of this company's system was, as usual, held in Manchester, convened by Mr. J. P. Bidder, on Monday last, when nearly 40 were present, Mr. G. G. Newman, the superintendent of the district, in the chair; Mr. Whittingham (Liverpool) occupied the vice-chair. These meetings assume the character of a dinner, and this one was universally admitted to have surpassed its predecessors in the completeness of its arrangements, the number of attendants, its creature comforts, and the genuine friendly spirit that pervaded the whole of the company, indicating thereby how good an understanding exists among the staff of this district, the largest in the system, and on this social occasion, as at all times, Mr. Newman must feel it no small pleasure to meet his officers. We know not a more effectual means for establishing a happy relationship between the members of any public service, than the coming together, personally, on an occasion of this description, and how much good to the governors and the governed is induced by them, it would be hard to determine. We understand the North-Western district is the only one which annually adopts these meetings; if so, we are sure if the example were more generally carried out, the company and the public alike must be benefited. The dinner over, the chairman (Mr. Newman) proposed the usual loyal toasts, and the Electric and International Telegraph Company, mentioning, in the case of the latter, that it was pleasing to know that its history had been one of uninterrupted and rapid progress. Mr. J. P. Bidder proposed "The Chairman;" in doing so, he remarked that the company, in their response, would manifest their approval of the virtues "honesty, uprightness, and manliness;" honesty, because his (the chairman's) actions had been consonant with his words, and in justification of their confidences; uprightness, because he was truthful in the administration of the principles of truth and justice; manliness, because he had ever been gentlemanly in his conduct towards all, in a district which he was proud to govern, and those present proud to belong; he had earnestly endeavoured to obtain right to his staff, and, therefore, all were glad to recognise him as their superintendent. Mr. Whittingham proposed "The Commercial Staff," which was responded to by Mr. Edmond (superintendent's office); also "The Engineering Staff," praising its perfectness, as instanced by the gale in December last, when this company was the only one open for two or three days, between Manchester, Liverpool, Leeds, and London; this was responded to by Mr. Noble (Lancaster). The "Chief Clerks" was then given, and responded to by Mr. Wade (Birmingham). An interest was given to this meeting by the farewell of Mr. Nadal (Manchester), who, after serving the company about sixteen years, had accepted a more important and lucrative appointment on one of the local papers. In his speech he compared telegraphing, in its early period, with the present time, which was peculiarly striking to all present. In a most touching speech, he said he could not leave a service under such circumstances, and having so many friends in it who he should esteem so long as he possessed an active heart, without many and deep regrets. As we have indicated, the meeting altogether was a most happy one.

THE electric telegraph now extends, by way of Russia, and within 200 miles of Kratchka—a frontier emporium, close to the Chinese empire—between which and Pekin, about 1,000 miles distant, there is a regular post established, so that now it would be quite possible to communicate with Pekin, from London, in a week.

PROVISION IN CASE OF ACCIDENT OR DEATH.—In a former number we noticed the fact that a poor man had lost his life while engaged in repairing a telegraph line at Chester, and expressed our regret that there existed no provision for the benefit of the men employed by telegraph companies as has been long the case with railway companies. Miss Oppenheim, the indefatigable secretary of the Telegraph Clerks' Provident Fund, has called our attention to the advantages offered to all those employed under telegraph companies by joining the above fund. The fund is not exclusively intended for clerks and manipulators, but for *employés* of every grade. We have carefully perused the rules of the fund, and the following extracts, we hope, will enable all those who have addressed us upon the subject to appreciate the advantages to be derived by becoming members of the institution:—

RULE 4.—*Sick Pay until Sixty.*

The following table shows the payments to be made every calendar month to insure 10s. weekly in sickness, and a proportion for days less than a week at the end of his or her sickness; the benefit and the payments continuing until sixty:—

Monthly Payments for the Assurance of Medical Attendance, &c., and an Allowance of 10s. per week during illness, until 60 years of age.

Age next Birthday.	s.	d.
15, and under 20	1	1
20, „ 25	1	2
25, „ 30	1	3
30, „ 35	1	4
35, „ 40	1	5

Any member who may be disposed to increase this allowance will be required to pay the increased rate, according to the age at the time of making such increase, *only on the amount of such increase.* Another table shows the amount of monthly payments to be made to secure an assurance of £10 at death:—

Age next Birthday.	s.	d.
15, and under 20	0	4
20, „ 25	0	5
25, „ 30	0	6
30, „ 35	0	7
35, „ 40	0	8

In addition, we quote the following special rules relating to endowments:—"Endowments of not less than £10, or more than £200, may be assured by members for themselves, or for their nominees, at any time, according to the tables. If any member, having assured a personal endowment, shall die before the payments have been completed, then the money received by the society shall be paid to the party nominated by the member, according to the rule below; or if no nomination has been made, it shall be divided among the relatives, according to the statute of distributions. If a member, assuring an endowment for himself or herself, cannot continue the payments, he or she shall give notice thereof to the secretary, and the committee shall thereupon take such measures for the repayment as they may think the case requires. If any member, having assured an endowment for a nominee, shall die before the payments have been completed, and notice thereof shall have been given to the society within six months of the death, together with a declaration in writing, stating that no person is willing to continue the monthly contribution, then the money received by the society shall, at the discretion of the committee, be paid to some relative for the benefit of the nominee, or retained until the period has elapsed at which the payments were to be completed, and then it shall be paid to the nominee; or should the nominee die in the interval, it shall then be paid to the person or persons appearing to the trustees to be entitled to the effects of the deceased nominee. If the nominee, on whose behalf an endowment has been contracted for by any member, shall die before the requisite payments have been completed, then the money received by the society shall be paid to the person or persons appearing to the trustees to be entitled to the effects of the deceased nominee. The secretary shall keep a book, in which a member may nominate in writing the person to whom the money paid for an endowment for himself or herself shall be paid on his or her decease, such person being the husband, wife, father, mother, child, brother or sister, nephew or niece, of such member (18 & 19 Vict., c. 63, s. 31). Any member may revoke such nomination by a written notice to that effect, signed by himself or herself; and it shall be the duty of the secretary to see the nomination erased. The member to pay 3d. to the Management Fund for each nomination or revocation." In glancing over the book containing the rules and regulations of the Telegraph Clerks' Provident Fund, we are glad to find that they have not only been approved of by Mr. Tidd Pratt, but by the directors of all the telegraph companies in England. The Electric and International Telegraph Company have had for some years a provident fund, towards which the company contribute a liberal sum yearly. In a future number we shall place before our readers an account of the benefits which the company's servants have derived from the existence of such a fund.

PHOTOGRAPHIC GROUP OF TELEGRAPHIC ENGINEERS AND ELECTRICIANS.—This photographic group is a reduction of a large composition picture, 35 inches by 22, executed by Mr. A. Brothers, of Manchester, comprising twenty-nine portraits of some of the leading telegraphic engineers and electricians of the day, as well as of other gentlemen connected with telegraphy. The picture has been prepared for a private gentleman, and most of the portraits were taken specially by Mr. Brothers, who has been eminently successful in grouping them in graceful and easy positions. The likenesses are all of them admirable, and as a specimen of photographic art we can commend it as excelling anything in the way of surface grouping we have ever seen. It is not an everyday occurrence; no less than thirty-two printings were necessary to produce the group, yet no defect throughout the print can be seen. Mr. Brothers explains that it is contemplated to form a second group, to include the most eminent men, the present picture being more of a private nature, and composed of some who have less claim to fame than the friendship of Mr. Brothers' client. A reduced copy of the picture is published.

THE KURACHEE AND CONSTANTINOPLE TELEGRAPH.—The *Scindian* describes the construction of the land succession of the Kurachee and the Constantinople telegraph—409 miles—to Guader in the Persian Gulf. Mr. Walton began the work on the 5th July, 1862, and the line was at work on the 30th April, 1863. The wire is carried over the Malan cliff, which overlooks the sea perpendicularly at an altitude of 2,000 feet. The exact height of the line at the eastern edge of the rock is 1,620 feet. The materials for the line over the Malan for a distance of more than ten miles had to be carried to the summit entirely by manual labour. The only pass to the top being on the western face, and too steep for camels. The country is destitute of water and vegetation, and only inhabited by roving Beloochees. The heavy surf prevented the landing of materials except at Omara, Pusnee, and Guader. The boats had to transfer their cargoes to canoes, which were shot through the surf. The line is constructed without a curve. A party of 318 men, of whom four were Europeans—the number afterwards increased to 636 in all—were engaged on the work. The cost of victualling the party by the Commissariat was Rs.29,822, and the total cost of the work was 2¼ lacs of rupees.

MISCELLANEA.

THE UNIVERSALITY OF ELECTRICITY.—Professor Faraday states that there is as much electricity employed to combine the gases in one drop of water as would, if instantaneously liberated, cause the brightest flash of lightning, sufficient to rend the majestic oak or destroy animal life. Such is the universality of electricity that it must be sought everywhere; flowing in an ever-constant stream from the centre of our system—the sun, it is taken up by the planetary spheres, each having its influence upon our earth; passing round our globe in ever-varying currents, it is the cause of terrestrial magnetism; it rules the storms; the clouds collect and are dispersed under its influence; descending lower, it stimulates vegetable and animal life—it is, in fact, vitality; it burrows in the bowels of the earth, causing the aggregation of metals into mines, and deposits precious stones by polar influence. Electricity is, therefore, universal, and every science must be exhausted before the limits of electricity can be ascertained.

MAGNETIC ETHER.—In a paper read at a recent meeting of the Royal Society, the Astronomer-Royal propounds a theory to account for magnetic atoms. The phenomena, in Mr. Airy's opinion, represents the movements of the magnetic ether, which he supposes to overspread the whole surface of the earth as an impalpable fluid envelope several feet in thickness. If we then conceive this magnetic ether to be subjected to occasional currents produced by some action or cecession of action of the sun, which currents are liable to interruption or perversion of the same kind as those in air or water, we have a theory by which the disturbances that occur in the observed phenomena of terrestrial magnetism may be explained.

SEEING AND BELIEVING.—The late Professor Daniell, having been invited to witness the first experiment made with the electric telegraph at the then newly-constructed station of the London and Birmingham Railway, on his return home immediately wrote to his friend, one of the inventors:—"I am quite surprised at, and almost at a loss to account for, the different effects produced upon my mind by *believing* and *seeing*. I had followed, as you well know, all your experiments from the beginning, and was intimately acquainted with both the principle and construction of the apparatus; but, nevertheless, when I saw it in action upon the Birmingham Railroad, I was struck as with something quite new; the facility with which I could myself immediately read signals communicated from a distance, and the simplicity of the means by which I saw you reply to them, and which I felt that I could myself master in five minutes, producing in me something like magic. I received immediate conviction of the possibility of conveying at a distance of 100 miles as quickly as a word could be spelled; and, upon cool reflection, I now feel satisfied that not only must the telegraph be adopted upon all railroads immediately [It was not adopted, however, for some years], but that it will very speedily be had recourse to upon an extensive scale for private communications between great commercial stations."

AN Englishman, lately arrived from Siberia, whither he had gone to arrange telegraphic communication with China, saw an unfortunate Irishman labouring in those snowy wilds. He was loaded with chains, and treated like any Pole; and it appears that he came to this grief through having deserted the British army before Sebastopol. Paddy was found wandering about in Central Russia. He was taken up, as, partly perhaps from an imperfect knowledge of the language, he could give no account of himself.

THE *Times*, in a recent article on the Schleswig-Holstein question, says, "Our readers, indeed, cannot fail to be struck by the remarkable way in which by the help of modern inventions they are carried along every morning with each turn of the dispute, and watch the successive changes with all the interest and excitement of spectators. In former times, when any issue of similar importance hung in the balance, we had no means of watching all the turns of the scales, and had to be contented with periodical announcements of the results. Events moved beyond our sight, and intelligence of them came to us as news of distant movements, the results of which might affect us, but with the actual and immediate course of which we could hardly interfere. Now, by means of the telegraph, all Europe watches the successive changes at the very seat of disturbance. Our intelligence this morning places before the public the movements yesterday afternoon upon the Eider, the state of the weather, the latest decisions of the German Powers, though not, we trust, the last resolution at Copenhagen. Nor is this change conspicuous only in giving us a more exciting and absorbing interest in the course of events. It has a most remarkable effect upon the course of events itself. Instead of its requiring, as in former times, weeks or even months of negotiation before the last resolutions of antagonistic Powers could be communicated to each other, the whole process is effected in a few days, and an army is transported from Vienna to the Eider in less time than it would have taken a few years ago to deliver a message from Berlin to Copenhagen. It was but last week that Austria and Prussia resolved upon the course they would take. The first step of presenting a summons to Denmark was made on Saturday, and the first contingents of the Austro-Prussian troops have already arrived on the scene of action. This rapidity of movement and instantaneousness of communication brings forces into play which were unknown in former times. It gives nations to a certain extent the invaluable power of seeing themselves as others see them before it is too late to be influenced by the knowledge. The aspect which every resolution and movement bears to foreign nations and Governments is immediately mirrored back to the agents. Important influence and advice may be brought to bear at almost every critical moment of the dispute, and may incessantly modify the course of action taken by a wise and considerate Power. We have reason to hope that some such good result may yet avail in the present danger in time to avert the all but commenced hostilities."

THE SUCCESS OF THE FIRST DOVER AND CALAIS SUBMARINE CABLE DESCRIBED IN THE JOURNALS OF THE DAY.—"Fate and Professor Wheatstone have for some time past been at odds as to the future fortunes of the human race, but now the Professor has got the best of it. 'A man can't be in two places at once,' says the old proverb, but, by the aid of electricity, any one of us may be in all the capitals of Europe at the same moment of time. We do not of course refer to the gross physical presentation of a man—to that portion of him which weighs fourteen stone and has the gout—but to his immortal essence, to his intellect, to his will. What matters it in what nook the *eidolon* may be thrust out of the way while the immortal spirit dabbles in shares on the Parisian Bourse, countermands the march of an armed host in Hesse, or gives its opinion of a painted window in the studio of a Munich artist? All these things a man can accomplish without moving from the Electric Telegraph Office in Charing-cross. The sea is no longer an obstacle to the instantaneous transmission of information. The deep waters have been reduced by scientific skill to be the highway of human thought — not, as heretofore, painfully conveyed in lumbering packages, and freighted upon large argosies which required half a year to put a girdle round the globe. Swift as thought on its first conception in a single human mind can thought now be flashed from one capital of Europe to another, and beget, at the distance of a thousand miles, the same sequence of ideas which plays at that very moment round the fretwork of the parent brain. We know not why, in strictness, the transmission of the electric spark 'full fathom five,' or five times fifty fathoms, beneath the troubled surface of the ocean, should affect the mind with greater awe than its instantaneous passage across the solid earth. Still this conquest gained by science over the waves must ever remain recorded as amid the greatest of human achievements since record has existed of the mighty feats accomplished by man. It is wonderful to reflect that, while the great ships 'reel to and fro, and stagger like drunken men,' far, far beneath their keels, amid the wrecks of former days, the current of human thought is evenly flowing on without disturbance or interruption. Let the ship begin to weigh her anchor in an English port, and, before three turns of the chain have been taken on the windlass, the announcement of her departure may now be flashed beneath the waters to the coast of France. The next moment another spark will convey the intelligence to the cities on the banks of the Seine, the Rhine, the distant Danube, and far within the inhospitable dominions of the Russian czar."

TO CORRESPONDENTS.

As information respecting Improvements, Extension of Lines, and Progress of New Undertakings will at all times be most acceptable, we hope that our readers will kindly render us assistance in our efforts to establish a Journal worthy in all respects of the great interest it seeks to represent, by furnishing us with brief notices of events and occurrences in connection with Telegraphy.

Communications intended for publication must be authenticated by the names and addresses of the writers; not neccessarily for insertion.

Letters relating to Advertisements are to be addressed to the Publishers. All other letters and communications to be addressed to the Editor of the *Telegraphic Journal*, 5, Suffolk-lane, Cannon-street, London, E.C.

The *Telegraphic Journal* can be had of Messrs. SMITH & Co., Strand; Messrs. DAWSON & Co., Cannon-street West; Messrs. KENT & Co., Paternoster-row, London. Messrs. HEYWOOD & Co., Manchester; at the various railway stations; and of all news-agents, &c., &c.; or it can be supplied, if preferred, direct from the Office on the following terms (paid in advance):—

	s.	d.
Quarterly	4	4
Half-yearly	8	8
Yearly	17	4

TO ADVERTISERS.

The *Telegraphic Journal* is the most effective medium for inventors, patentees, contractors, manufacturers of insulating materials and electrical apparatus to submit their various specialities to the consideration of secretaries and managers of telegraph or railway companies, and other persons engaged in electrical and telegraphic pursuits.

Clerks, assistants, manipulators, and instrument makers, seeking employment, &c., will find the *Telegraphic Journal* a ready means of making known their requirements.

Advertisements must be delivered to ensure insertion before SEVEN O'CLOCK on Thursday evening in each week. The charges for Advertisements are—

	£.	s.	d.
Whole page	4	4	0
Half ditto	2	10	0
Quarter ditto	1	7	6
Four lines and under (single column)...........	0	3	0

Single Advertisements from the country must be accompanied with stamps in payment.

THE ATLANTIC TELEGRAPH.

THE renewed effort about to be made to realise the object for which the Atlantic Telegraph Company was formed, is a subject of no inconsiderable importance to the public at large. We believe that a great amount of misapprehension exists as to the motives which induced the Company to relinquish their intentions of manufacturing and submerging the cable in the present year; of this we are assured, that the Company sought the best advice, the result of which was to defer the manufacturing and laying of the cable until next year. The Company very properly appealed to the members of the late Telegraph Committee of the Board of Trade as to their opinion of the practicability of submerging a cable across the Atlantic ocean, and as to its permanency when laid, and they were encouraged to proceed in their great undertaking by the receipt of the following certificate, now for the first time made known in England, signed by all the members of the said Committee:—

London, 13th July, 1863.

We, the undersigned members of the Committee who were appointed by the Board of Trade in 1859 to investigate the question of submarine telegraphy, and whose investigation continued from that time to April, 1861, do hereby state as the result of our deliberations, that a well insulated cable, properly protected, of suitable specific gravity, made with care, and tested under water throughout its progress with the best known apparatus, and paid into the ocean with the most improved machinery, possesses every prospect of not only being successfully laid, in the first instance, but may reasonably be relied upon to continue for many years in an efficient state for the transmission of signals.

DOUGLAS GALTON, F.R.S. C. F. VARLEY.
C. WHEATSTONE, F.R.S. LATIMER CLARK.
W. FAIRBAIRN, F.R.S. EDWIN CLARK.
G. P. BIDDER, F.R.S. G. SAWARD.

The Company in the meantime secured the valuable services of Professor Thomson and C. F. Varley, Esq., to guide them in the construction of a core capable of transmitting the requisite number of messages to render the undertaking a remunerative one; the result of those gentlemen's investigations are given in the following communications addressed to Mr. Cyrus W. Field:—

THE ELECTRIC AND INTERNATIONAL TELEGRAPH COMPANY.

(Incorporated 1846.)

Telegraph-street, London, E.C., July 1st, 1863.

My dear Sir,—I have, during your absence in America, completed the apparatus contemplated at the time of your departure last December, and have tested them on various lengths of submarine lines. Enough has been ascertained to leave no doubt that we shall be able to telegraph through an Atlantic cable direct from Ireland to Newfoundland at the speeds given in the annexed table, depending upon the size of the copper conductor, the weight of gutta percha, and the length of circuit. The speeds indicated in this table might be much increased by a proper system of coding.

I am, my dear Sir, yours very truly,

(Signed CROMWELL FLEETWOOD VARLEY.

From my experience on the old Atlantic cable, both before and after its submersion, and during the time it was being laid, and from estimates founded on the general theory, of which I have shown the principles in papers published in the proceedings of the Royal Society, I feel perfect confidence that the speeds stated by Mr. Varley in the preceding letter are attainable with the general European Morse Telegraphic Alphabet. I have no doubt that considerably higher speeds may be practically realised by adopting some system better adapted to meet the peculiar circumstances of a great submarine telegraph.

(Signed) WILLIAM THOMSON.

To the above communication is added the following interesting Table:—

OPERATION of the Electrical laws affecting the speed of working through long Submarine Cables, exemplified in the weight of insulation in proportion to copper, required to attain given rates of transmission per minute. Ascertained by CROMWELL F. VARLEY, Esq., Electrician to the Electric and International and to the Atlantic Telegraph Companies; and W. THOMSON, Esq., LL.D., F.R.S., Professor of Natural Philosophy in the University of Glasgow.

TABLE,

Showing the speed of working through an Atlantic Cable from Ireland to Newfoundland, a distance of 1,640 *Nautical Miles.*

Allowing 15 *per cent. for slack, will make the actual length of Cable in circuit* 1,880 *Nautical Miles.*

Weight of Copper in lbs. per Nautical Mile.	Weight of Gutta Percha in lbs. per Nautical Mile.	Total Weight of Core per Nautical Mile.	Words per minute through 1,880 Nautical Miles.
107	261	368	3.5
143	224	367	4.
225	275	500	5.8
275	325	600	7.
214	522	736	7.
286	448	734	8.
300	400	700	8.
325	375	700	8.25
350	350	700	8.4
400	400	800	9.5
400	425	825	9.8
400	450	850	10.03
321	783	1104	10.5
450	450	900	10.7
400	475	875	10.25
400	500	900	10.44
429	672	1101	12.
428	1044	1472	14.
572	896	1468	16.

Having ourselves had the honour of assisting in carrying out the important experiments under the Committee of the Board of Trade, we are glad to have this opportunity of expressing our concurrence with the statements which have guided the Atlantic Telegraph Company in their glorious and noble efforts to extend the advantages and benefits of submarine telegraphy, feeling confident that success must be the result.

THE MALTA AND ALEXANDRIA CABLE.

THE obstructions which have deprived the community from time to time of the advantages of telegraphic communication with India, *viâ* Malta and Alexandria cable, have also created a considerable amount of uneasiness and doubt in the public mind, as to the practicability of ever rendering submarine telegraphy a permanent and remunerative institution. This is owing, to a considerable extent, to the absence of information as to the causes of such interruptions, and the reason for the delay which on each occasion has taken place in their removal. We have already, in a previous number, referred to the very unsatisfactory manner in which one of the parties to the lease for working the line have performed their obligations, in not having a vessel always ready at Malta or Alexandria, fitted with the proper appliances for raising and repairing the cable

at once, instead of having to despatch a vessel from England for the purpose. The Council for India have wisely adopted the precaution, in the case of the Persian Gulf cable, of having a steamer, fitted with the necessary machinery, always to be kept in a central and convenient port. Of course such precautions can only be made available for repairing cables submerged in shallow water. All the injuries hitherto, which have occurred to the Malta and Alexandria cable, have been in shallow water, and in localities where the nature of the bottom and the character of the coast were known to have been by no means favourable to the permanency of the cable. The *Malta Times* of the 21st ult., in announcing the interruption of the line, states:—"The injury is supposed to exist not far from Benghasi, on the east side; and it is satisfactory to mention that there is every reason to believe it is of a purely mechanical nature, as the stoppage was quite sudden, and took place, without any previous deterioration or fluctuation of electric force, whilst a message was being sent through the line to Alexandria. Every effort is being made to discover the exact locality of the damage, which, it is considered, very likely to have been caused by some ship's anchor dragging, during the late violent storms on the coast." It is further stated, "that an officer from the station at Benghasi, attended by a proper escort from the Caimakan, had been despatched with instructions to proceed along the shore to see if signs existed of any vessel having been driven on the coast, and, if necessary, to prosecute his researches a hundred miles to the eastward." We find that there were several of Her Majesty's ships at Malta, and no doubt machinery might have been easily placed on board, had there been such machinery in readiness at Malta, or any of the other stations. Admiral Smart, we are informed, was most ready in offering any assistance in his power, but observed that *men of war*, for obvious reasons, were ill adapted for cable ships, and he feared that nothing could be done till the arrival from England of a vessel fitted with all the appliances for the purpose. So that the provisions of the lease, authorising the loan to the lessees of any of Her Majesty's ships which might be at Malta, or at any adjacent port, are utterly useless. We trust that the vessel which has just left England, for the purpose of repairing the injury, will remain at some convenient port, so as to be ready in case of emergency; or that a fresh survey be made, and that those portions of the line which are known to be laid on a rocky and dangerous bottom, be removed to more favourable positions, in which the cable will be less liable to be subjected to mechanical injury, either by attrition, or by being severed by dragging anchors.

SELF HELP.

Sir,—I have read "J. R. O.'s" letter and also your article on "Amenities."

It cannot be wondered at that the continental clerks are more scientific and generally better educated than our own. Read the list of subjects in which candidates are examined, and consider how very few, even of the sons of wealthy men, could pass such an examination. The reason is that science, being required, is more cultivated abroad, and that, owing to the comparative scarcity of employment and the lower scale of expenditure in living, young men of superior birth and station are content with low salaries.

Were continental salaries given, and continental acquirements expected here, how many of our circuits would be manned?

But when it comes to *work*, we can fearlessly assert that our own staff is far more energetic and does its work far better than those across the water. Not because they are *not scientific*, but because they are more persevering and business-like; because they are, in fact, English.

"J. R. O." is mistaken when he says telegraph clerks have neither books nor encouragement; but he is more mistaken if he thinks *encouragement*, or the giving formal instruction, will make good men out of bad ones.

Every one must help himself; all our great men have made themselves and ever will. When a clerk or workman shows a desire to improve and exhibits talent, I will take upon me to say that there is no superior officer in the whole service who will not be but too glad to answer his questions and bring him forward. For why? good men are scarce and are urgently wanted. All our best clerks, with few exceptions, have been messengers, while the most useless and troublesome fellows on the staff are those who have influential friends and who bring a packet of testimonials. Why so? Instead of trusting to themselves, these last lean on what their *friends will do for them*, and rely on the influence they can bring to bear to screen their defects.

Our clerks' hours of duty, even at the longest, are far less than those of persons of similar rank engaged in trade. The genius of their employment, unlike that of the shop, leads to and encourages self-improvement, while, in fact, very many have time enough, and to spare, during their hours of duty to improve themselves. But what is too often the case, the clerk who has eight or nine hours of leisure, during which he is obliged, however, to remain in his office, and is almost driven to study even to pass the time; this man is always inaccurate and behindhand in his returns and accounts—has never *time*, he says, even to give the slight items of information for which he is occasionally called upon.

Other men, hard worked fourteen or more hours a-day, *make time* for self-improvement. Where there is a will there is a way.

I have been induced to offer these few remarks to my fellow telegraphists by reading the report of a presentation of a service of plate, worth between four and five hundred pounds, to a late chairman of a railway company on his retirement.

He is the son of a working man—his schooling, such as it was, finished at his eleventh year; he then earned a living as he could till he was seventeen, was then apprenticed to a carpenter and for some time worked at his trade. This gentleman not only has made his fortune—not by speculation but by steady industry—but has also educated himself and *made time* to write some twenty volumes on learned and difficult subjects.

Let our young friends look round and see if they can name *any one* whose rise has been brought about by what others have done for him, by his being "coached" or "crammed" with electrical or technical knowledge.

There is no royal road to learning or to success; it must be fought for and won by individual energy, perseverance, and contempt of difficulties. How many "impossibilities" have been overcome in a moment when an order has been issued that the impossible thing *must be done*.—Yours,

AMICUS.

THE LAST TELEGRAPHIC FEAT.

In our last number, under the above heading, we inserted a few interesting particulars relating to the transmission of the speeches of the honourable members for Birmingham, from that town, by telegraph, to the metropolis. For some days the "coming event" had been a subject of much speculative discourse in all the great telegraph and newspaper establishments of the metropolis, especially as it was believed that the speech of Mr. Bright would not only be a lengthy one, but that there would be a tilt against the *Thunderer* of Printing-house-square; and in this, at all events, they were not disappointed. We have stated that the speeches contained no less than 49,000 letters, and that the whole were transmitted to London, and delivered at the offices of seven newspapers before 3 o'clock, A.M.; the whole operation in London being super-

intended by Mr. Boys, the Chief of the Intelligence Department of the Electric and International Telegraph Company, and at Birmingham by Mr. Wade. The difficulty experienced in reading the reporter's copy; the care and labour involved in the transmission itself; the copying out in London, and the collection of the slips coming by the different wires; and the supervision necessary before the copy is delivered into the hands of the messengers of the fourth estate, create in the telegraph room no inconsiderable amount of bustle and excitement, on the night when the great politicians of the north are displaying their oratorical powers before their admiring and enraptured constituents. Our readers will better understand the enormous amount of labour required of the officers in charge and the manipulators, on such an occasion, when they glance over the alphabetical code employed in the transmission of intelligence with the Morse instrument, which we append. Every *dot* and *dash* require a distinct operation. The *dot* is effected by a quick tap on the key, and the *dash* by a slow one. Any of our readers may be able, after a short practice with their hands upon a table, to converse by such means with great rapidity.

The great advantage offered by recording telegraph instruments over needle and dial instruments is, that they impress, or print, on continuous paper strips, clear and distinct marks, representing the messages transmitted, whereas the latter only produce transitory signs, subject to misinterpretation and omissions.

ALPHABETICAL CODE FOR THE MORSE INSTRUMENTS.

The length of a dot being taken as a unit, the lengths of the different signs will be as follows:—

A dash = 3 dots.
The space between the signs of a letter = 1 dot.
" two letters = 3 dots.
" two words = 6 dots.

SUBMARINE CABLES.

I.

THE more the causes which have led to so many disastrous failures in submarine telegraphy are sifted and inquired into, the stronger becomes the conviction that the old and favourite plan of strengthening and protecting our cables with iron, exposed to the corrosive action of sea water, is utterly inadequate for the object in view. In fact, experience has proved that to envelope our cores in naked iron is to lessen rather than to increase their permanency. It is remarkable that, until lately, this prolific source of danger to cables has received, comparatively speaking, but little or no consideration; that while a vast amount of ingenuity has been expended upon the construction of instruments, in investigating the laws which govern the transmission of the electric current (with a display of mathematical lore which has seldom or ever been paralleled), and in the preparation and manufacture of the best insulating material, &c., very little attention has been paid to the external requirements of our cables.

In almost all the cables hitherto submerged—with the exception of the Isle of Man and South of Ireland cables, and the Persian Gulf cable, now about to be laid—the insulating cores have been sheathed with iron wires; and in the numerous attempts which have been made from time to time to repair or recover cables which had failed, it was found that the iron wires had been completely eaten away by corrosion, and the insulator damaged in some cases by the sharp points of the severed wires, and by attrition, &c. Mr. Latimer Clark, in his report to the directors of the Red Sea Telegraph Company, states:—"The electrical condition of the copper and gutta-percha core was generally so good, that when properly covered it is fit for resubmersion; but, owing to the entire absence of all protection, the iron was corroded away; that the cable, when suspended over rocks or submarine valleys, gave way spontaneously, breaking up in short lengths." The evidence of other experienced telegraph engineers may be adduced confirmatory of the inapplicability of unprotected iron sheathing in both shallow and deep water.

We have carefully perused the voluminous evidence given before the Government committee, consisting of some 5,000 questions and answers, occupying no less than 280 folio pages. No less than 44 witnesses were examined, yet the danger from the corrosion of the iron sheathing had been foreseen but by few. We place before our readers some of the statements as they appear in evidence.

The late Mr. J. W. Brett, in answer to Mr. Saward, secretary to the Atlantic Telegraph Company, states, with respect to the Dover and Calais cable, which had been recently taken up to be repaired:—"In some parts the iron is very much corroded where it has come in contact with the lime and the chalk rocks." Mr. Canning, who had examined the same cable, adds:—"In many places the outside wires appear to be very bad indeed, and eaten away, but to a very small extent in others; it is very much rusted, and, in fact, so much so, that there is a very small portion of wire holding or remaining." Mr. W. H. Preece, engineer to the Channel Island Telegraph Company, mentions also "several instances of corrosive action having impaired the iron sheathing of the company's lines," and adds:—"Perhaps you would allow me to observe, in speaking of corrosion of cables, that I am decidedly of opinion that no cable should ever be submerged upon a rocky bottom, or upon a bottom likely to be swept by tides, without having some exterior shield to protect the iron from this corrosive action." Mr. R. S. Newall says:—"From our experience in laying the Red Sea cables, and finding that the iron wire is completely corroded off it in various places, I think that it is worse than useless putting it in any water except shallow water, and near the shore, to guard against ships' anchors. We found the same thing occur in the Holyhead cable, that the iron wires were completely corroded off it." Mr. F. C. Webb, who has had considerable experience in the laying and repairing of submarine cables, in a paper read by him before the Institution of Engineers, gives the following as the result of his experience:—"When the cable was buried it was found to be in perfect preservation, the galvanised surface being as clean and good as when the cable was first laid; whilst in those places where it lay on the surface it was eaten through, extending in many parts for one or two feet in length, to such an extent that it was only held together by a portion of only one outside wire. The gutta-percha and hemp were undisturbed, retaining the impression of the outer wires, thus showing that the decay was not caused by mechanical injury, but by oxydization,

probably the result of galvanic action. The galvanised surface had also entirely disappeared where the cable was not buried. This decay, where the cable lay on the surface, fully accounted for the invariable fracture of the cable seaward of the ship when it was grappled for and lifted outside the bank." And again, Mr. Webb, in his evidence before the Government committee, states:—"In some places the outer wires are much eaten by rust, and at such places a very slight strain would break them. I have seen places on the rough grounds where the outer covering was completely eaten through for a few inches, whilst a few yards off from the same spot the cable was quite sound and strong."

Mr. C. F. Varley, in his report of his efforts to recover a portion of the Atlantic cable on the coast of Newfoundland, states:—"The recovered cable varied in condition very much, and what is most important is, that even those portions which came out of the black mud were so perished in numerous patches, that the outward covering parted on board during the process of hauling in." In fact, it has been found that in all attempts made to recover or repair iron-sheathed cables, whether in the Red Sea, the Mediterranean, or the Atlantic, the corrosive action of the water has in every instance, to a more or less extent, impaired the strength of the cable.

THE VICISSITUDES OF A TELEGRAPHIC ENTERPRISE.

In order to ensure the success of any great national undertaking, to develope any new enterprise, or to establish any discovery tending to the public weal, it appears necessary that a sacrifice should be offered to propitiate the Fates. No grand work has ever been accomplished without disasters having occurred in the outset of the most discouraging character. When Stephenson first ran his engine upon the Liverpool and Manchester line, nothing less than the mutilation of one of his best friends would suffice to inaugurate the new era in locomotion The reverses which Brunel met with in his "Leviathian" project are still fresh in the memories of most of our readers; and it will not be out of place here, just to revert to the calamities which befel the Atlantic cable in 1858, whereby half a million of public money was sunk in the bed of the ocean, and confidence in the practicability of submarine telegraphy shaken to its foundation.

We extract the following interesting particulars from a very ably written paper on "The Atlantic Cable and its Teachings," by Mr. W. Crookes, which appears in the *Quarterly Journal of Science*:—*

A great amount of misconception prevails respecting the now defunct Atlantic cable, and we propose to disinter from the ponderous official documents some portions of its history which are not generally known.

The "Niagara" and "Agamemnon" having met and joined their respective halves of the cable in the middle of the Atlantic, started thence and proceeded, one to Newfoundland, the other to Valencia Bay, in Ireland, electrical signals being constantly passed from one ship to the other. At one point, when nearly 400 miles had been paid from each ship, the electrical signals became very weak, and the tests applied by the electrician on board the "Agamemnon," showed that there was defective insulation at a very remote part of the cable. The fault then seemed to get better, and in about an hour the cable tested as usual. Three days afterwards, when about 560 miles had been paid out from each vessel, considerable irregularities were observed, the signals becoming weaker, until it was reported from the electrical cabin that they had ceased altogether. They shortly afterwards returned, and gradually improved for some hours, when they became as strong as ever. In fact, on the evening of this day (August 2), the signals from the "Niagara" were reported to be stronger than they had been previously. Other irregularities in transmission were afterwards observed, but the general working of the cable seemed good, and on referring to the memoranda taken by the electricians at the time, we find the signals spoken of as "good" in the morning of the 3rd August, "first rate" about the middle of the day, and "perfect" in the evening. The next day we have reports of constant signals from one ship to the other, and the memorandum "all right," is repeated several times. On the 5th of August, at 2.10 A.M., the "Niagara" signalled that she had paid out 1000 miles of cable, and at 3.50 A.M., the "Agamemnon" had paid out the same quantity. At that time, intelligible signals were passing through the 2000 miles of cable, from one end to the other, and in a few hours each ship was safely at anchor. Thus, then, the possibility of connecting the two continents by an electric cable was proved.

* John Churchill & Sons, New Burlington-street.

On the 10th of August, the first words were sent from America to Ireland, but although the whole day was occupied in such messages as "Repeat, please," "Please send slower for the present," "How do you receive?" "Please say if you can read this," "How are signals?" "Please send something;" and the second day was occupied in similar messages and requests to "Send alphabet," and "Send V slowly," Valencia, like a coy maiden, refused to respond to these entreaties. On the third day, Valencia showed signs of thawing, and condescended to obey the request contained in the following message sent from America:—"If this received, send battery current in one direction five minutes." The next day when America signalled—"Send word Atlantic," Valencia was able to reply, "Atlantic:" (this was the first word read in America.) We then find several words from Valencia in answer to American entreaties, but during the whole of this day, America was signalling to Valencia such messages as these:—"We receive currents, but can't read you," "Can't read," "You must send slower, as some of your dots do not show on most delicate detectors," "We get your currents, but so irregularly, that we cannot read them; will you examine your key well?" On the fifth day, Valencia thawed a little more, and actually asked America to "Send faster;" but although several long messages were sent on that day from America, only isolated words were received in reply. On the seventh day, Valencia and America seem to have arrived at a better understanding with each other, and Valencia asked, "Can you take a message?" with the warning, "You must repeat each sentence in full." Upon receiving an affirmative reply, Valencia telegraphed:—"Directors of Atlantic Telegraph Company, Great Britain, to Directors in America: Europe and America are united by telegraph. 'Glory to God in the highest; on earth peace, good-will towards men.' Repeat back faster. Queen's next." After America had telegraphed back the above message, the Queen's message was sent. This consisted of ninety-nine words, and occupied altogether sixteen hours in its transmission; many parts were repeated over and over again, and the whole message was signalled back to ensure accuracy. After this, owing to the greater delicacy in the reading instruments, and especially to Professor Thomson's beautiful reflecting galvanometer, several long messages were sent backwards and forwards; America, however, always doing the greater part of the talking. On the tenth day very good signals came, and Valencia asked for the messages to be sent faster. The telegram respecting the collision between the "Arabia" and "Europe," was sent on that day from America, and it was followed by the President's message to the Queen.

Professor Thomson was at this time constantly engaged upon experiments, and the result of these was that the cable spoke much more intelligibly, complimentary messages being sent between the directors and many public men, and several long directions on the details of working the instruments. From this time the cable seemed to improve, and on the twenty-second day the memorable Government messages were sent to America, countermanding the return of the 62nd and 39th Regiments, thereby saving to the British Government the sum of £50,000.

On the 30th of August, Mr. Field telegraphed from America, as follows:—"Early in the morning of September 1, Please send me message that I can read at the celebration that day, and another on the 2nd that I can read at dinner that evening." Accordingly on the 1st of September, Valencia telegraphed the following message to C. W. Field, New York:—"The Directors are on their way to Valencia, to make arrangements for opening wire to public. They convey through cable to you and your fellow-citizens their hearty congratulations and good wishes, and cordially sympathize in your joyous celebration of the great international work."

Up to this time the condition of the line may be said to have undergone slight improvement. Several long and important communications had been sent through it, and it was on the eve of being formally opened for commercial purposes, when, without any ascertained cause, a collapse took place, and the Atlantic Telegraph suddenly became defunct; its death being the more ignominious when we take into account the message, in the utterance of which it expired. From this date no other sentence could be forced through, and with the exception of isolated words and signals during the month of September, all attempts to restore communication failed. As late indeed as October 20th, eight words of a sentence were spoken through the cable from Newfoundland to Valencia, but this was owing to the employment of recklessly energetic battery power, and may be looked upon as the spasmodic twitchings of a galvanized corpse, rather than healthy vitality.

The Atlantic Telegraph project is again attracting public attention. Mr. Cyrus W. Field (one of the leading spirits of the undertaking) is again amongst us, full of hope, and ready to embark once more in the gigantic enterprise. We have learned many lessons of wisdom by the last sad failure; and it is confidently believed by those who have the best means of judging, that the renewed efforts about to be made to unite the old and new world will be attended with perfect success.

The Coming Man.—The *New York Tribune* states that a telegram was recently despatched to the Federal army, directing to whom the command of a brigade was to be intrusted, and that the operator at the telegraph station declared the person selected to be Amjyrdkowasejcw Dcabxpcop.

THE INTERNATIONAL EXHIBITION, 1862.

(*Continued from p.* 53.)

TABLE C.—PART II.—CABLES WHICH HAVE BEEN SUCCESSFUL FOR SOME TIME, BUT ARE NOT NOW WORKING.—*October*, 1862.

No.*	Date when laid.	FROM	To	Conductors. No.	Conductors. Size per B.W.G.	Size of Insulator per B.W.G.	Outside Wires. No.	Outside Wires. Size.	Length of Cable in Statute Miles.	Length of Insulated Wire in Statute Miles.	Maximum depth of Water in Fathoms.	Weight in Tons per Statute Mile.	Length of time the Cables have worked.	OBSERVATIONS, AND PROBABLE CAUSES OF ULTIMATE FAILURE.
1	1850	Dover	Calais	1 wire.	—	—	None	None	About 25	25	30	—	1 day.	No protection of any kind: is called a partial success because it established the possibility of telegraphic communication between England and France.
2 2a 2b	1853 to 1855	England . . . (Three similar Cables)	Holland . .	1 do.	16	1	10	8	360 Aggregate.	360	30	2	5 to 6 yrs.	So frequently broken by anchors that it was found cheaper to recover these cables altogether, and replace them by a very strong cable, No. 20 in list, part I. One of these cables was relaid between Holyhead and Howth, when No. 3 cable in this list was abandoned.
3	1854	Holyhead . . .	Howth. . . .	1 do.	16	0	10	8	75	75	70	2	5 years.	Iron wires rusted so much after five years as not to admit of repairs at moderate cost.
4	1855	Varna	Balaclava. . .	1 do.	16	2	None	None	355	355	300	0·1	9 months.	Cause of failure not known. The only unprotected cable, or insulated wire, successful for any time.
5	1855	Balaclava . . .	Eupatoria. . .	1 do.	16	2	12	18	—	1				
6	1857	Varna	Constantinople .	1 do.	16	2	12	?18	170	170	Shallow	0·75	4 or 5 yrs.	Too light for shallow water.
7	1857	Sardinia	Bona	4 strands.	16	5	18	11	150	600	1500	1·85	3 years.	Not tested under water; iron wires quite rusted off in some places; 80 miles recovered.
8	1857	Sardinia	Corfu, *viâ* Malta	1 strand.	15	1	18	15	700	700	1000	0·9	1 year to 18 mths.	Not tested under water, after being covered with iron; cause of failure not known.
9	1858	England. . . .	Channel Islands	1 do.	14	1	9	6	102	102	60	2·5	2½ years.	Too light for position in which laid; strong tides, rocky bottom; repaired eleven times, and abandoned, owing to cost of repairs.
10	1858	Ireland (Atlantic)	Newfoundland .	1 do.	14	00	126, *i.e.* 18 strands of 7, No. 22, wires.	14	About 3000	About 3000	2400	1·0	3 weeks & 4 days	Not tested under water; probably faulty before laid; outer covering soon rusted. The 3,000 miles includes cable lost in 1857. Copper 93 lbs., gutta-percha 227 lbs. per mile.
11	1859	Singapore . . .	Batavia . . .	1 do.	12	0	18	16	630	630	20	0·94	About 2 years.	Too light; was continually broken by anchors, or maliciously by natives; frequently repaired.
12	1859 1860	Suez (Red Sea and India)	Kurrachee . .	1 do.	12	0	18	16	3500	3500	1910	0·94	6 to 9 months each section.	Five sections. Not tested under water after being covered; outer covering soon rusted through. Never good at one time from end to end. Copper 156 lbs., gutta-percha 184 lbs. per mile. Four miles of wire, insulated with india-rubber, laid at Kurrachee, were found to be totally decayed in 1862. The gutta-percha, whereever examined, was sound.
13	1859	Spain . . .	Africa (Ceuta) .	1 do.	14	00	126	14	25	25	—	1·0	Not known.	
14	1859	England . . .	Isle of Man . .	1 do.	16	2	10	6½	36	36	30	2·5	3 years.	The first cable in which the outer iron wires were protected against rust by hemp and bitumen; temporarily broken; will probably be repaired.
15	1859	South Australia .	Tasmania. . .	1 do.	16	1	10	8	100	100	60	2	—	Same cable as No. 35, part I. Chafed by rocks, and found difficult to repair, owing to nature of ground, and probably to the absence of proper appliances.
16†	1859	Liverpool . . .	Holyhead. . .	2 strands.	16	3	12	6	25	50	14	3·1	—	Broken by ships' anchors continually.
17	1859	Syra	Candia. . . .	1 strand.	14	1	16	15	150	150	—	0·89	2 to 3 yrs.	Has been abandoned and picked up, because it did not pay for the repairs required. A hemp cable was temporarily tried on this line.
18	—	Across Mersey. .	—	—	—	—	—	—	3	3	—	—	12 months	About three miles of cable, with wires insulated by india-rubber, were laid across the Mersey, and between various docks. This cable was removed, owing to constant accidents. The india-rubber is said to have remained perfect.
				Totals					9406	9882	These totals can only be taken as approximations, as the exact length of several of the cables is not accurately known.			

* The numbers do not represent the exact order in which the cables were laid, and are only given for convenient reference.

† Some part of this cable is again at work.

TABLE C.—PART III.—TOTAL FAILURES.

No.	Date when laid.	FROM	To	Conductors. No.	Conductors. Size per B.W.G.	Size of Insulator per B.W.G.	Outside Wires. No.	Outside Wires. Size.	Length of Cable in Statute Miles.	Length of Insulated Wire in Statute Miles.	Maximum depth of Water in Fathoms.	Weight in Tons per Statute Mile.	Length of time the Cables have worked.	Observations, and Probable Causes of Ultimate Failure.
1	1852	Holyhead . . .	Howth. . . .	1 wire.	16	—	10	1	75	75	70	0·45	—	Hemp or jute rope in three strands; no iron; india-rubber next copper, covered with gutta-percha.
2	1852	Portpatrick . .	Donaghadee . .	2 wires.	16	8½	None	—	17	84	160	—	—	Faulty insulation. This cable was all recovered.
3	1852	Portpatrick . .	Donaghadee . .	5 do.	16	2	12	2	15	75	160	4·8	—	Cut away after this length had been paid out. Subsequently recovered.
4	1854	Holyhead . . .	Howth. . . .	1 wire.	16	0	10	8	65	65	70	2	2 days.	
5	1855	Sardinia. . . .	Africa	6 wires.	16	1	12	1	40 to 50	240 to 300	About 800	8 to 7½	—	The vessel laying this cable was taken out of her course by a French steamer, and the length was consequently insufficient. A considerable portion was subsequently recovered.
6	1855	Cape Ray . . .	Cape North . .	3 do.	16	2	10	4	30	90	360	—	—	A sailing vessel towed by a steamer was used in the attempt to lay this cable. Bad weather came on, and the cable was cut to save the ship.
7	1855	Sardinia. . . .	Africa	3 do.	17	4	10	8½	About 160	480	1500	8·7	—	
8	1859	Candia	Alexandria . . .	1 strand.	13	1	18	16½	Say 150	Say 150	1600	0·89	—	Several unsuccessful attempts were made to lay this cable—once with a hemp cable, which failed from a defect in insulation (not tested under water); again with a light iron-covered cable, broken accidentally. The length of insulated wire lost is not known.
				Totals					557	1239	These totals are very rough approximations.			

NOTE.—The writer is much indebted to the French, Spanish, and Swedish Governments, to Sir Charles Bright, Mr. Latimer Clark, and Mr. Cromwell Varley, as well as to the Exhibitors, for the assistance given him in compiling table C. He regrets to feel that many additions and corrections might still be made.

Comparative Table of Inches and Numbers in Birmingham Wire Gauge.

2. *Unsuccessful Cables, and Causes of Failure.*

Hitherto successful cables only have been spoken of; but the great extension and success of submarine cables has been accompanied by some great failures. A cable successfully laid across the Atlantic in 1858 worked for three weeks, and then failed altogether; a specimen of this well-known cable is exhibited by Mr. Brett.

A cable laid from Suez to Aden worked for nine months, and then failed a few days before a second section was completed from Aden to India. At the present time all this cable is useless, except a short piece from Suez to Jubal.

A specimen of the core of this cable is shown by the Gutta-Percha Company, and the Dacca-Pegu cable exhibited by Mr. Henley exactly resembles the outer covering. A similar cable was used to join Singapore and Batavia; this has been repeatedly broken, but being in shallow water, has been from time to time repaired. Malta and Corfu, and Malta and Cagliari were for many months connected by a very similar cable, the core of which is exhibited by the Gutta-Percha Company, and various other lines, successful at first, have now been totally abandoned. Not one of these cables was tested under water after manufacture, and every one of them was covered with a sheathing of light iron wires weighing in the aggregate only about 15 cwt. per mile.

These two peculiarities are amply sufficient to account for any failure which has hitherto occurred. In fact no electrical test will show the presence of flaws in the insulating cover of a wire unless water or some other conductor enters these flaws, and establishes an electrical connection between the outside and the inside of the cable. It is not surprising that a few flaws are always to be found in every long cable. It cannot be expected that hundreds of miles of a thin soft covering shall either be made perfect in the first instance, or remain uninjured while being covered with iron wire.

Whenever, therefore, a long cable has been submerged without having been previously tested under water, defects have generally been detected shortly after submergence; these defects, holes, or flaws have then been too often subjected to the action of powerful batteries, which by the heat and chemical action they develop, enlarge the fault, and cause the gradual but sure destruction of the cable. The other cause of failure named, viz., the small size of the wires used to cover the unsuccessful cables, is curiously connected with the omission of the necessary test under water. Engineers were afraid to keep these cables under water during manufacture lest the light iron wires should be weakened by rust, and break during submergence. They were kept dry, and in almost every instance the cables were submerged safely, and as it was thought successfully. It was supposed that after submergence the iron wires might rust away without danger to the core. Precisely the contrary has occurred; so long as the iron wires lasted the cables frequently continued to work in spite of faults in the insulating cover, but sooner or later the iron wires of all these light cables rusted away in parts, and as soon as this took place they one and all broke up into short sections. This fact has been observed in the Atlantic, the Black Sea, the Red Sea, and the Mediterranean, in shallow water, and in depths of 1,000 fathoms. The wire does not rust uniformly off the cable, but is eaten completely off at certain points, and here the gutta-percha and copper frequently sever. Engineers are not agreed as to the cause of these fractures; some think the cables have have been laid in a state of tension, so that they contract when the outer wires yield at any point; others suppose that the cables are, as it were, festooned from ridge to ridge along the bottom, but neither explanation seems to the writer fully to account for the universal occurrence of this phenomenon, which is worthy of further examination. Meanwhile, the use of large iron wires seems a sure guarantee against this danger, for as yet no cable covered with wire of the large gauges has ever parted in the manner described.

As an additional security several cables have, as already mentioned, been protected by a bituminous covering. It is hardly necessary to add that no engineer now thinks of allowing a cable to be laid which has not been constantly and carefully tested under water.

There are now more than 5,000 statute miles of cable, containing more than 9,000 miles of insulated wire, in successful operation. By far the greater portion lies in depths of less than 100 fathoms, and it may be safely said, that no improvement in design is required for these shallow-water cables.

3. *New Forms proposed for Deep-Sea Cables.*

It cannot yet be said that the problem of the best form for long deep-sea cables is successfully solved.

Some of these cables have certainly been successful, but many have entirely failed, chiefly owing to the causes already mentioned. The remedy of heavy iron wires is hardly applicable to this case, owing to the great weight, cost, and risk they entail. Many new forms have consequently been proposed for use in deep sea, but many of them are founded on a misconception of the defects of the usual type. The difficulty of laying the common cable in deep water has been much exaggerated; very few cables have broken during submergence, and of those few, most have been broken by accidents such as might occur with any form of cable.

The usual cable can be laid with ease in any depths less than 1,000 fathoms, and can with equal ease be recovered from those depths so long as the outer wires remain sound. The danger of kinking has also been much over-stated: with proper appliances cables very seldom kink, and not one kink in a hundred does any harm. If small iron or steel wires could be efficiently protected against rust, there would be little fault to find with the common type of cable.

The Gutta-Percha Company, M. (United Kingdom, 3,000), show an excellent but expensive specimen in which each iron wire, or rather strand, is protected by gutta-percha.

W. Hooper, H. M. (United Kingdom, 2,915), shows specimens in which hard vulcanized india-rubber is used for the same purpose, and also a specimen in which the aggregate iron sheath is cased in a cylinder of vulcanite; this latter form entails the use of his preparation of india-rubber as an insulator.

T. Allan, M. (United Kingdom, 2,860) proposes to surround a solid copper conductor with the steel wires, and to cover the whole with gutta-percha as an insulator in the usual way, dispensing with the outer iron wires altogether, but using instead a canvas serving saturated with marine glue and asphalte.

He thus obtains a light cable which will support upwards of 7,000 fathoms of its own length in water. Looked upon as an electrical instrument, such a cable would be inferior to a similar copper strand equal in weight to his combined strand, and covered with an equal quantity of gutta-percha; but this inferiority could be made up by an increase in the weights of the materials, and the combined strand is so proportioned as to reduce the inferiority as much as possible. Mr. Allan's cable, on the other hand, is certainly less liable to be broken or injured by stretching than a mere insulated copper strand would be. It is generally thought unsafe to leave the outer surface of the insulator so unprotected as Mr. Allan proposes, and it is to be feared that the two dissimilar metals inside the sheath might lead to injurious chemical action. It is to be regretted that Mr. Allan's cable has never been practically tested. If the steel wire could be obtained in sufficient quantities, Mr. Allan's would be cheaper and lighter than the usual cables.

Siemens, Halske, & Co., M. (United Kingdom, 2,959), exhibit specimens of a submarine cable intended chiefly for use in deep water, and described by them as follows:—

"The insulator is covered with a double layer of hemp-strings of the strongest material, saturated in Stockholm tar, laid on spirally and under considerable tension, the twist of the two layers running in opposite directions. It is finally covered by a flexible brass or copper sheathing composed of bands of sheet copper or brass, put on spirally under the influence of great pressure, and with each succeeding turn overlapping the

preceding. The covering thus produced resembles the scales of a fish, affording perfect protection without being deficient in flexibility."

Messrs. Siemens further say that the phosphoretted copper or brass used will not corrode in sea water, but remain in perfect condition for a great number of years, and that the tensile strength and low specific gravity of the cable will, together with its durability, allow the cable to be lifted in very great depths, and after the expiration of many years. Messrs. Siemens have certainly produced a light strong cable, not liable to kink, easily handled, and affording fair lateral protection. It stretches less than one-half per cent. with half its breaking strain, and a cable only ⅜ in. diameter will not break with less than fifteen cwt. The cable could therefore be easily and safely submerged. It is, however, doubtful whether Messrs. Siemens' opinion as to the durability of the sheathing can be justified. It is found very difficult to obtain any two specimens of copper or brass, of similar electrical properties; and any equality of composition between the various bands of metal used, which cause galvanic action to be set up, resulting in the rapid decay of some parts at least of the thin metal protection. The hemp, if left unprotected by metal, would rapidly decay or be eaten by animals, and the cable in this state would be in the very same conditions as have proved so fatal to cables covered with light iron wires.

Experience may prove that these fears are unfounded, and Messrs. Siemens state that they have for some months past kept samples made with strips of various coppers in sulphuric acid and water without producing any destructive galvanic action. Most engineers will probably agree in wishing that this novel form of cable should be tried, although they may not be prepared to accept the responsibility of recommending its adoption.

This form of cable seems well adapted for various uses on land—as for military lines, electric target wires, mines, &c. The cost of the covering is about the same as that of a light iron wire sheathing, but the new form is much lighter and more easily handled.

(*To be continued.*)

PRIVATE TELEGRAPHS.

Many schemes have been devised, from time to time, for relieving large towns of the inconveniences arising from the increase of vehicular and passenger traffic, consequent upon the development of trade and commerce; and among them the telegraph is not the least important. The city of London has completely outgrown itself, and every means must be adopted to lessen the difficulties encountered in the overcrowded streets of the metropolis. We have subterranean railways, pneumatic despatch companies, and a telegraph network employed to attain this end, but until the public take advantage of the means thus placed at its disposal, very little improvement can be anticipated. A prejudice still exists against the adoption of the telegraph, by private firms, which we shall endeavour to remove, by pointing out the advantages which would result from its more general employment.

Business in large establishments is frequently subject to considerable delay, in consequence of the difficulty experienced in communication with branch offices, by special messenger, or through the post. The pecuniary loss thus incurred can only be estimated by contrasting the working of the telegraph with the now old-fashioned system of porterage.

The Houses of Parliament, the Government offices, the police and fire brigade stations of the metropolis, are all united by the wire—and in this particular instance we note a degree of sagacity manifested by our public functionaries, excelling the acumen displayed by some of our most spirited capitalists, who are generally the first to adopt any great improvement or application—money market operations are flashed to and from all the cities of the United Kingdom; and, indeed, the telegraph has become indispensable in our commercial relations. In several instances manufacturers have connected their various factories with their city offices by a private line of telegraph, and are thus enabled to give orders for the execution of work immediately on receiving instructions from their customers, a desideratum especially commendable to all persons engaged in extensive mercantile enterprises. No difficulties are experienced, no errors occur (but such as can be rectified in an instant). The beautiful instruments of different inventors, employed in this branch of telegraphy, are easy of manipulation, and may be worked by any clerk, foreman, or youth of ordinary intelligence. Notwithstanding these recommendations the telegraph has not been made subservient to the requirements of city men to any considerable extent. By the old method it becomes necessary to write out orders and to dispatch them by a porter, who, travelling by the quickest route, is often unable to reach his destination under several hours, involving no small loss of time, and incurring great expense.

Now, what has been done by the aid of the telegraph, in the instances above enumerated, we would urge upon the favourable consideration of all firms having depôts remote from the central office. Contractors for the execution of works in any part of the metropolis would find the telegraph a most valuable adjunct to their staff, and we venture to affirm that its employment generally for intercommunication would diminish the inconveniences inseparable from a voluminous correspondence, avoid disappointment consequent upon many a fruitless journey, and admit of a reduction in the working expenses of large establishments.

One great objection to the adoption of the telegraph by individuals is the first cost; but this does not avail in London, for wires may be rented of the various companies from £2 per mile per annum; and any one can, therefore, have his exclusive line for a comparatively trifling amount. Persons engaged in trade will thus be enabled to form a tolerably correct estimate of the outlay that would be necessary to connect their various places of business by the telegraph; and we hope that many, who have hitherto ignored the private line on account of its expense, will be led to acknowledge its immense utility, and to avail themselves of one of the most effective means of relieving large towns of superabundant traffic.

NEW PROCESS OF ELECTRO-DEPOSITION.

We have great satisfaction in announcing to our readers the success of a most important invention, consisting of improvements in the art of silver plating and gilding by electro-deposition by means of new apparatus, the invention of Mr. S. Moore, of 34, Liverpool-street, Bishopsgate-street, and for which he has obtained Her Majesty's Royal Letters Patent.

The great demand which has of late years arisen for this class of goods, and the advantages which the public have derived from their use, are ample reasons for the attraction of the notice of scientific investigators, and consequently numerous attempts have been made from time to time to improve that art, which has hitherto been considered almost perfect.

The chief advantages of Mr. Moore's process are, that he obtains, with a rapidity not hitherto known, a fine deposit of silver or gold, possessing a surface as smooth as glass, the character of the deposit being superior to that acquired by the ordinary slow deposit; and also that he can at any time ascertain the exact amount of silver or gold deposited on the goods by means of an apparatus, which obviates the necessity of removing the silver or gold plate or the articles from the bath, and subjecting them to the process of weighing. Consequently the goods can be left in the bath undisturbed from beginning to end of the electro-deposition, and need only be removed when the exact quantity of metal has been deposited thereon. In fact, when the desired quantity of silver or gold has been deposited, the apparatus is so constructed and arranged that the wires leading from the batteries to the bath become disconnected, and the action ceases, the goods receiving no further deposit.

It needs no comment to those acquainted with the process of depositing metals of every kind by electrical action to impress them with the vast importance of this new discovery, as they will eagerly and gladly appreciate and profit by its advantages, and the facilities it affords of at once overcoming the many difficulties that have always presented themselves to those who practice the art either by way of trade or otherwise.

Indian Population of Central British America.—Great misapprehension exists as to the numbers of the Indian population of Rupert's Land. They do not exceed 40,000 in all. The number inhabiting the prairies and plains of the lake Winnifreg and Saokatchewan districts do not exceed 20,000 at the present time. Under proper management the Indians would become most useful and tractable protectors of the proposed telegraph line described in our fourth number. Once impressed with the idea that it is something supernatural, they would cherish it, protect it, and reverence it as a "Maniton," or superior spirit, exercising a control over their fortune, and even lives.

REPORT OF THE DIRECTORS OF THE ELECTRIC AND INTERNATIONAL TELEGRAPH COMPANY.

In presenting the periodical statement of accounts, the Board are again enabled to congratulate the shareholders on a steady improvement in the Company's revenue.

The causes which led the Directors to anticipate this result have continued in operation during the half-year. The receipts from American messages, *viâ* the South of Ireland, have much increased. The continental business has been considerably developed, and from the improved arrangements and extension of the system throughout Europe, and the East, a further expansion of this important field of traffic may reasonably be expected. An increased number of stations in Great Britain has also swelled the income, and the efficiency with which the service has been conducted, arising mainly from the superior condition of the Company's lines, has, the Directors believe, contributed largely to retain the confidence and support of the public.

The revenue of the Company from all sources for the half-year amounts to £137,150, exceeding that of the corresponding period of 1862 by the sum of £20,076.

On the ordinary working charges there is little to remark; but a perusal of the Electrician's report attached, will explain the cause of a large increase in the cost of maintenance. Extensive renewals have been effected, which have enabled the Company to perform their service with greater regularity and despatch.

The total expenditure for working charges and interest on debentures, amounts to £86,582, leaving a surplus of net profit on the six months of £50,568. Your Directors recommend a dividend of £3 10s. per cent. for the half year on the stock, and on the new shares (£5 paid), which will amount to £34,120, and leave a balance of £16,447.

This balance is larger than it has been usual to carry forward, but the Directors have no hesitation in recommending that it be placed to the credit of the trust fund for the reasons so frequently given, and so generally approved by the shareholders. The perishable nature of the best submarine cables, and the necessity of being provided with the means of replacing them, imperatively demands that this fund, which was exhausted in laying the new cable to Holland, should be replaced by accumulations from revenue.

The proprietors will remember that at their last meeting it was announced that the Directors had disposed of a portion of their leasehold property in Founders' Court for £16,000. In the June capital account the Company stands debited with the item "value of house property in London £10,161." Your Directors have therefore written off this amount, thereby reducing the capital to that extent, and have carried the balance (£5,839) to the trust account.

This fund on the 31st December, 1863, amounted, with interest, to £6,529; the two appropriations named above will increase it to £28,816.

After a service of fifteen years, your secretary, Mr. J. S. Fourdrinier, has retired, and in consideration of his long and faithful duty, and the zeal he has always exhibited in the interests of the Company, the Directors have unanimously resolved to recommend a pension of £300 per annum being voted to him. A resolution to that effect will consequently be submitted to the meeting.

Mr. Henry Weaver, one of the most experienced of the Company's officers, has been appointed to succeed him.

With deep regret the Board has to record the death of one of its oldest and most valued members, Mr. Thomas Critchley.

The following Directors retire by rotation at the present meeting: —Lord Alfred Paget, M.P., W. H. Smith, Esq., jun., Lieutenant-General Wylde, C.B., Mark Huish, Esq., and the Right Honourable Sir John Lawrence, K.C.B.; and being eligible, offer themselves for re-election, with the exception of Sir John Lawrence, whose appointment as Governor-General of India has deprived the Board of his active and valuable services.

The Directors have carefully considered the policy of filling the vacancies caused by the death of Mr. Critchley and the retirement of Sir John Lawrence, but; as the Board still numbers fifteen members, they have decided that it is not desirable to increase it, and they have, therefore, in pursuance of a clause in the Company's Act for that purpose provided, reduced the number to fifteen.

Robert Grimston, Chairman.

Electrician's Report.

January 20th, 1864.

Gentlemen,—Your circuits continue in excellent order. During the past autumn we experienced gales of great severity, and during the early part of December a hurricane traversed the country. Although the pressure of the wind reached the almost unprecedented force of 43 lbs. on the square foot, scarcely any of your poles were broken.

The timber between Newton, Carlisle, and Lockerbie on the west coast, and between Edinburgh and Berwick on the east coast, has undergone a thorough repair, it having been almost entirely renewed. These links between Scotland and the rest of your system are particularly exposed, and more interruptions have been experienced from gales over these sections than elsewhere. In carrying out these renewals the opportunity was accordingly taken so to remodel these lines as to secure them as much as possible against these periodical interruptions; the result has been that during the December gales not a single instance occurred of the wires becoming deranged over these sections.

The new wires erecting between London and Newcastle and London and Edinburgh have compelled us to replace nearly the whole of the timber between Peterboro' and Newcastle. The value of the precautions which experience has taught us to adopt when renewing a line was fully demonstrated in December last, when the new line stood admirably, not a single pole being broken.

The Dunwich Zaandvoort cable, two wires of which were defective at the date of my last report, was repaired on August 6th. As this cable has been broken several times within a distance of nine miles from Dunwich, the opportunity was embraced when repairing these wires to relay the greater portion of this section of the cable by means of the spare cable you had in store.

The slender single wire cable between North Wales and Dublin, has at last failed, and I do not think it can be profitably repaired, the iron covering being entirely consumed in many places by the action of the sea. We have therefore established direct communication between Liverpool and Dublin through your Wexford cable, which with the Isle of Wight cable continues in the same excellent order as when I last reported.

The two new wires between London and Liverpool are in full operation. The two between London and Manchester are partially so, the latter two, being completed with the exception of about one mile through the Stafford and Crewe Yards. These wires will be open before another week elapses.

The new wire to Edinburgh will be working early in February next, as also that from London to Newcastle.

The system of establishing direct communication between your important stations so as to save manual transmission, and the consequent clerical errors and delays, is steadily progressing. London now communicates direct with nearly every principal town of Great Britain, most of which possess the means of direct intercommunication.

The steady improvement in the insulation of your lines has considerably expedited the rate of transmission.

Since my last report the following works have been completed:—

The erection of the telegraph on the Inverness and Perth Junction Railway, on the Conway and Llanrwrst Railway, on the Brecon and Merthyr Railway, on the Milford Railway, on the Dumfries, Lochmaben, and Lockerbie Junction Railway, on the Romsey Railway, on the Skipton and Colne Branch of the Midland Railway, on the Falmouth Extension of the Cornwall Railway, on the Swansea Extension of the Vale of Neath Railway, and on the St. Ives and March section of the Great Eastern Railway. Two new circuits have also been opened between London and Liverpool.

The following new works are in progress:—

The erection of the telegraph on the Hereford, Hay, and Brecon Railway, on the Caermarthen and Cardigan Railway, on the Newtown and Machynlleth Railway, and on the Aberystwith and Welsh Coast Railway; besides these there are in hand numerous additions to the existing system of telegraph for the various railway companies.

	Dec., 1863.	June, 1863.	Increase.
Miles of Line	8,230	8,006	224
Miles of Wire	39,042	36,921	2,121
No. of Instruments	4,489	4,163	326

Cromwell F. Varley,
Electrician.

TELEGRAPH TO INDIA COMPANY (LIMITED).

The third ordinary general meeting of the shareholders of this company was held at the offices, No. 62, Moorgate-street, on Monday last, for the purpose of receiving and considering a report of the directors, for declaring a dividend, and transacting the ordinary business of the company; the chair being occupied by W. Dent, Esq.

The Secretary having read the notice convening the meeting, and the report having been agreed to be taken as read,

The Chairman said that he was glad to be able to congratulate the shareholders on the favourable state of their company, which was more than at one time was expected, after the failure of the attempt to repair the cable. Had that attempt been successful they would have received from 25 to 30

per cent. more on their capital than they had. The attempt having failed the cable had become worthless whilst submerged, and they had failed in obtaining any offer for it because the expense of taking ships round the Cape, to raise it, would be greater than its value when raised. If it could have been repaired its value to them would have been very great. He was glad to inform them that their assets had realised favourably, and he hoped that, when the Malta and Alexandria cable were in active work, the shareholders would receive a remuneration for the money they had invested, either by leasing it to another company, or working it themselves. (Hear.) The more the telegraphic system became known by the Egyptians, the more it would be used, and as a large portion of the traffic was local, and greatly on the increase, the working would be much more profitable, and there would be every probability of the shareholders getting out of the company without loss. When the Alexandrian line was at work their earnings were £250 per week, but he was sorry to say that the Malta and Alexandria line had again given way; the contractors and lessees (Messrs. Glass & Elliot) had, however, sent out a vessel to repair it, which they hoped to do in a very short time. By the interruption of the communication for about two months Messrs. Glass & Elliot were entitled to deduct from the company £200, but they had allowed that to stand over, reserving to themselves the right to claim it at any future time, as, according to the conditions of their lease, they were entitled to deduct a certain amount whilst the cable was not working, on account of the reduction of their receipts. He regretted that the chairman of the board was not present, he having gone to India; and, therefore, in his absence, he would move the adoption of the report, with the statement of accounts.

Admiral HALL having seconded the motion,

A SHAREHOLDER wished to know if there was any probability of getting up the cable, and what would be the use of it?

The CHAIRMAN, in reply, said that it would not pay the expense of raising it.

In reply to a question about the sale of the house at Aden, no mention of which appeared in the accounts, the Chairman said that it had been sold for £1,800, but had not yet been paid for, therefore no mention had been made of it.

A SHAREHOLDER said there appeared to be some little confusion as to the revenue and capital account, the assets of the capital account—£8,564 15s. 10d.—having been transferred from the revenue account; so that, practically, the dividend would be paid out of the capital account. This he did not object to, so that they got their money at some time or other. He wished to know whether, with the balance on the revenue account of £2,544, the directors would be able to pay 6d. in the pound.

Mr. BILLING said that, if the £2,544 were divided, it would certainly give them 6d. in the pound, but it was so small that it would not be worth doing it. He did not like the £200 due to Messrs. Glass & Elliot standing over. It appeared as a gift to the company, and yet it was not so, and hereafter it might embarrass them. As a shareholder, when he found that there was no probability of recovering the line he had given up all idea of receiving anything for his money, and had written it off as lost; but, after what the chairman had stated, he thought there might be some hope, and he should be glad to receive anything which the directors could give him. (Hear.) He believed that the directors were working for the company entirely without remuneration, but he hoped that eventually they would receive some pay for their services, and so soon as the company was in anything like a position he should be pleased to propose their payment.

The CHAIRMAN said that the Pasha of Egypt proposed to extend the land line to Aden, but it was not the intention of their directors to go any further than they had already. As to the balance of £2,544, he considered it would not be well to touch that, as some of it might be required for repairs, and to enable them to retain their rights, instead of surrendering them to other individuals. When payment was made for the house at Aden that would be carried to the capital account, and he proposed that the amount remaining beyond the dividend should be carried to the same account. Like Mr. Billing, when he found that the attempt to recover the cable had proved fruitless, he had written the amount off as a loss, but still he believed they would yet get their capital back, or, at any rate, get their 5 per cent. whilst the company lasted, which would not be a bad investment.

A SHAREHOLDER said that when the line was first proposed it was promised to pay a large dividend; he believed, however, that the capital would ultimately be realised, but the large gain had not been obtained at present.

F. C. GAUSSEN, Esq., remarked that Sir Charles Bright had informed him, that none of the cables put down at present were looked upon as being very secure, and that these interruptions might be more frequent than hitherto.

A SHAREHOLDER thought that the shares were influenced detrimentally from the fact that they were £2 shares, that £1 had been paid upon them, and that they were liable to a call for £1 more. The consequence of this was, that their shares were only worth 5s. per share; whereas, if they were made £1 shares, paid-up, they would be worth 15s., and thus add to their value in the market.

The CHAIRMAN, in reply, said that there would be no further call upon the shares unless there was a good prospect of using it, and if so the shareholders would be called together to sanction it. The directors would take the suggestion with regard to the shares into consideration, and take legal advice upon its practicability. With respect to the Syrian Telegraph Company, negotiations had been entered into with them to connect the Egyptian line with the Syrian, but there was no intention of proceeding any further with it. If Messrs. Glass & Elliot felt inclined, of course they were at perfect liberty to do so. He believed they had consulted the Pasha as to allowing them a concession to carry on the line, and they were ready to pay 7½ per cent. for it.

The report, including the proposal of a dividend of 5 per cent., was then put to the meeting, and carried.

Mr. SEBAG proposed "that P. P. Blyth, Esq., F. C. Gaussen, Esq., and J. F. Leith, Esq., be re-elected to fill the office of directors of the company." As directors these gentlemen gave their services for the benefit of the company, and they were very much indebted to them. Whenever the company might realise anything he should certainly propose that they be paid, but if they were now willing to retain their position, as before, he should feel pleasure in supporting them.

Mr. BILLING seconded the motion, remarking that, whenever the question should be brought forward for their remuneration he should be most happy to support it.

The motion having been put, was carried unanimously.

Mr. SEBAG proposed, and Mr. ROBINSON seconded, "that J. A. Franklin, Esq., and A. S. Wildy, Esq., be auditors for the ensuing year, on the same terms as the directors, namely, gratuitously."

Messrs. Billing and Taylor having offered to act as auditors in the event of those gentlemen declining, the motion was put to the meeting, and carried unanimously.

Thanks having been voted to the directors for the way in which they had conducted the affairs of the company, the proceedings terminated.

CORRESPONDENCE.

THE PNEUMATIC APPARATUS.

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—When I addressed you from here I naturally anticipated a reply from Mr. Andrews, contradicting my statement.

Mr. Andrews' instruments were manufactured by Mr. Sandys and Messrs. Reid Brothers, and the books of the Submarine Telegraph Company will sufficiently show at what dates his various experiments were resolved into systems; for when instruments are ordered in sufficient quantity to supply the working of all the long lines of a Company, it would necessarily lead to the conclusion that the experiments and models had been satisfactory to their projector.

If Mr. Andrews thought of the pump so long previously, he could not have been greatly impressed with its merits, or he would not have caused such immense expenditure for dozens of sets of apparatus of other descriptions. His systems, with their accompanying complete sets of instruments (say ten or twelve of each sort) had been already changed three times previously.

1st. A balanced magnetized bar, similar to a scale beam, and working on knife edges or slight springs, with a single coil under each end. The working current was zinc from one end and copper from the other end of the cable.

2nd. A magnetized horse-shoe armature working between two electro-magnets; the upper magnet being an ordinary one working by repulsion; the lower one a continuation of a permanent magnet (something after Hughes's style). The writing current was as above; but there was an instantaneous current *of an opposite description sent before.*

3rd. The instrument named in Mr. Andrews' last letter, viz., an ordinary Morse with a second electro-magnet in the printing circuit. This second electro-magnet set loose an escapement movement, which was brought close to its stop by the ordinary clockwork. The writing current was copper at both ends of the cable, and the reversal (*sent after the working current in this instance*) zinc.

When I joined the Company in 1860, six or eight of No. 1 were on the shelves in the workshop. Mr. London had just completed the mounting of No. 2 system on all lines. A few months afterwards No. 3 was mounted, and No. 2 went to keep company with No. 1. Again a few months and No. 3 had to join Nos. 2 and 1, being replaced by the pump.

And yet Mr. Banks says the suggestion and its entire working out was proposed before I returned from the Mediterranean. If I mistake not, he used to add my name when speaking of the pump-handle and relay.

Mr. Guy's memory must be very retentive in this particular instance, for so little did he understand about mechanics, that whenever I went to Aldersgate-street I was invariably addressed direct to the workmen on that account by Mr. Guy himself. Is it likely Mr. Andrews would have taken the matter, or even a portion of it, out of the hands of the regular mechanician, who had, according to his own assertion, already gone through the entire working out of the apparatus, to entrust it to one who had nothing whatever to do with that department?

Now, sir, so much stress being put on the fact of the pneumatic relay having been worked out before my return, I think this is a fair challenge. Let Mr. Guy produce a single account (I appeal to the Submarine Telegraph

Company's books in this instance also) relative to any portion of a pump-handle or relay, not only before my return, but for some months afterwards, I will bow my head and retire. If he cannot do so, he may just as well talk of Mr. Andrews having mooted a steam relay.

Mr. A. makes a most gratuitous remark when he says *he* engaged me. He had no more right to engage anyone than I have myself, and, in fact, he was absent at the time—abroad, I believe. My nomination took place in the usual way, *i.e.* through the Secretary and Board of Directors. I am labouring under the disadvantage of being forcibly absent from town, or I could have furnished you with fuller details and further corroboration.

Your No. 4 only reached me on Friday, or I would have answered sooner.—Yours very obediently,

J. R. France,

Off Yarmouth, 1 Feb., 1864. Acting Engineer, Sub. Tel. Co.

To the Editor of the Telegraphic Journal.

Sir,—Will you allow me to say a word about the pneumatic relay? This relay I always supposed was unquestionably the invention of Mr. France, and if anything had been wanting to confirm the supposition in my mind, I should have found it in the following simple circumstance. Shortly after Mr. Andrews ceased to be engineer to the Submarine Telegraph Company I was appointed superintendent of the Cromer station, whence the longest cables leave the English coast, and it fell to my lot to have to remove from some of the most important lines, and replace with the pneumatic relay instruments which Mr. Andrews had invented, or which, at least, I know him to have had constructed *subsequent* to the invention of the pneumatic instrument. I was surprised at the time to find instruments so much more cumbrous and inefficient still upon the lines, and attributed it to a very natural partiality on the part of the late engineer for his own offspring over that of Mr. France. It is not possible to suppose that this invention would have been thrown aside by its inventor to give place to another far inferior in every respect, unless there had been some reason for his so doing.

I remain, Sir, your obedient servant,

T. Harwood,

Cromer, 30 Jan., 1864. Superintendent of the Cromer Station.

MR. SIEMENS' BATHOMETER.

To the Editor of the Telegraphic Journal.

Sir,—I have read some time since, with great interest, an account of Mr. Siemens' "Bathometer." Though I am not of opinion, giving results as it does, differing only 10 per cent. from the truth, that it can ever be regarded as a proper substitute for deep-sea sounding lines, with which we seek not less the ascertainment of the *character* of the bottom than the actual depth, yet I do think that its utility would be very great, if applied on board such steamships as are obliged to make quick passages under hazardous circumstances, (witness the late accident at Cape Race,) for there the transition from deep water to dangerously shallow, might probably be at once recorded by the instrument, without any diminution of speed. Founded, as that instrument is, on correct mathematical principles, it may, undoubtedly, be brought to greater perfection than it has yet attained, and this will, I am sure, be quickly done if the attention of its talented inventor be again given to the subject. J. H. Selwyn, Capt. R.N.

THE BONELLI TELEGRAPH.

To the Editor of the Telegraphic Journal.

Sir,—In answer to your correspondent, I beg to assure him that the accidental loss of a wire, or even two wires, does not at all affect us in the disastrous manner he supposes. Should he desire occular demonstration of this I shall be happy to afford to him, if he cares to come and see, how comparatively independent Bonelli's system is of "loss," "contact," and all the thousand ills "terrestrial" and "atmospheric" telegraphy is heir to.

I am, Sir, your obedient servant, Henry Cook.

Angel-court, Throgmorton-street, Feb. 3rd, 1864.

P.S.—With regard to the expense, &c., of constructing and maintaining a line of five wires, I beg to say that the Bonelli system is only intended to be introduced on circuits which are fully able to support the outlay, and that the extra cost (if any) will be fully compensated for by the great saving effected in all other departments.—H.C.

To the Editor of the Telegraphic Journal.

Sir,—Your correspondent, "D. P. L.," is in error when he states that the old double-needle instrument possesses advantages over the Morse in rapidity of transmission. In a fair trial made a few years ago, when their respective powers were severely tested, Mr. Culley, in his work, gives the following as the result:—"The highest speed on a circuit of a little under 200 miles was:—Double-needle, 35 words per minute; Printing (Morse), 38 words per minute. Average, if between two and three hours' continuous work, reporting a speech of Mr. Bright:—Double-needle, 24.3 words per minute; Printing (Morse), 26.5 per minute. And for a circuit of more than 400 miles:—Printing, average speed, 24.5 words per minute; clerk reading from the manuscript of the *Times* reporter, not always very legible." L. M. O.

THE PAYING-OUT OF SUBMARINE CABLES.

To the Editor of the Telegraphic Journal.

Sir,—I beg through your valuable journal to be allowed to warn Mr. Siemens against the inevitable consequences of making a great fly-wheel by putting the cable on a drum *in* a ship. Not only does this scheme utterly fail to meet the dangers inseparable from the motion of a ship on the sea, but it is a true fly-wheel, which a cylinder supported *in* water is *not*. The diameter, when full and empty (of cable), is subject to much greater variation, and the benefits gained by the use of a large and long cylinder in this direction are totally lost. Let no one, therefore, say, that if this attempt fails any conclusion can be fairly drawn that the floating cylinder will also be found useless. J. H. Selwyn, Capt. R.N.

RAILWAY TRAIN SIGNALLING.

To the Editor of the Telegraphic Journal.

Sir,—The subject of railway train signalling is undoubtedly one of very great importance, and well deserves a fair discussion in your columns. We have several systems in operation on the various railways, but most of them are exceedingly complicated, and cannot be much relied upon; and, I believe that the plan originally suggested by Mr. Fothergill Cooke still maintains its ground as the most certain and simple in its action and character. As almost all our great lines of railway can now be traversed in all directions by trains without the necessity of changing engines, carriages, or officers, it is exceedingly desirable that there should be uniformity in the mode of electric signalling, as there is in that of signalling by the semaphore, and that the adoption of electric signalling should be made compulsory by an Act of Parliament for the better security of the lives of the travelling millions. Another important application of electricity would be to effect communication between the guards and the engine-drivers. The many serious and fatal accidents which have occurred in consequence of the absence of such a plan of communication points out the necessity of its adoption being rendered compulsory on the part of the companies.—Yours obediently,

2nd Feb., 1864. J. L. Martin.

THE LAST TELEGRAPHIC FEAT.

To the Editor of the Telegraphic Journal.

Sir,—The notice of "the last telegraphic feat" in your Journal of the 30th January has afforded considerable amusement to the clerks of the Magnetic Telegraph Company here—myself among the rest,—the rate at which Messrs. Scholefield and Bright's speeches were transmitted being considered a very poor performance indeed, even for the Morse. 12,000 words on three wires in five and a half hours, is equal to about 13 words per minute on each. Now, on the instruments chiefly used by the Magnetic Telegraph Company—namely, Sir Charles Bright's bell—30 words per minute is considered a very moderate rate for the transmission of messages, and to manage a column of news in an hour on one wire, the clerk receiving and writing for himself, is of frequent occurrence. I think, sir, that the merits of this instrument are not at all known or estimated at a proper value, or such *feats* would not be recorded. Any one acquainted with both systems must admit that the bell is by far the quickest single-wire instrument. I am aware that Cooke and Wheatstone's double-needle instrument is reputed to be the quickest at present in use; but the fact of two wires being required as well as a writer, is a great objection to it. So long as telegrams are written by the hand, I consider it impossible, for any practical purpose, to get a superior instrument, as it can be wrought at a speed that would perplex the quickest writer to keep up to. Hoping you will give this a place in your Journal, I am,

Glasgow, 2nd Feb., 1864. A Bell Clerk.

A SUGGESTION.

To the Editor of the Telegraphic Journal.

Sir,—I have only recently had an opportunity of seeing your journal, and I must certainly congratulate you upon having produced a thoroughly representative organ. I am no stranger to the management of a newspaper, and, of course, know some of the difficulties experienced in the *sanctum sanctorum*; and I am persuaded that, if they were more generally known, editors would often receive valuable co-operation from their readers, especially in class literature. It occurred to me that you must either employ a large staff, or else be obliged to labour most assiduously over newspaper files, culling the scraps which you publish from time to time under the head of "Telegraphic News." Now, I have a suggestion to make whereby you will be saved a vast amount of trouble, without inconveniencing others. You have supporters in all parts of the country, each in the habit of perusing his local journal. Every paper, at times, has notices of interest to telegraphists, and if you could but induce some of your numerous subscribers to cut and post you the said *morceaux*, you would never be without a good column of news. It is hardly to be expected that even an editor can know everything that transpires in the United Kingdom and abroad, unless he has a staff of "special correspondents;" and, therefore, I am sure you would esteem any service thus rendered by your readers.—I am, Sir, yours,

Yorkshire, 2nd Feb., 1864. H. Elp.

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—Has not the earth wire, bound round the cross arms, instead of direct to the insulators, been in use for some years by the old telegraph companies? I am, Sir,

London, 1st February, 1864. A LADY TELEGRAPHIST.

[Perhaps some of the gentlemen employed under the old companies will reply to our fair correspondent's note.—Ed. *T. J.*]

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—Can any of your readers inform me, through the medium of your valuable Journal, what the component parts of the solution are with which to prepare the paper for printing instruments, that it may be used *dry* instead of damp, and oblige,

Your obedient servant,

Holyhead. SEMPER.

TELEGRAPHIC NEWS.

THE PROVIDENT CLERKS' FUND.—Mr. Cyrus W. Field has generously contributed the sum of £5 towards this excellent fund, and favoured the secretary with introductions to some of the leading friends of telegraphy in America.

WE are rejoiced to learn that Mr. E. B. Bright, the manager of the British and Irish Magnetic Company, is recovering from a very dangerous illness. The greatest interest was felt at Liverpool whilst his state was precarious, as he is greatly respected in that city for his talents and high character. During his illness he has been most ably attended by Dr. Fitzhenry, of Waterloo; Dr. Cameron, of Liverpool; and Dr. Stephen Ward, of London.

THE UNITED KINGDOM TELEGRAPH COMPANY have now extended their wires to Newcastle, and, in the course of a short time, they intend formally to open business in the town. The company have now communication with nearly all the large centres of population in England.

UNIVERSAL PRIVATE TELEGRAPH COMPANY.—The aerial cable belonging to the above company, and which runs parallel with and above the houses on the south side of Cannon-street, E.C., was severed by the fire which took place in Turnwheel-lane on the 3rd instant. It appears to us that the company's arrangement in suspending their cable directly above the buildings renders the operations of their lines exceedingly precarious and uncertain.

LONG AND SHORT CIRCUIT.—Messages between Hamburgh and Copenhagen are now transmitted through London, twice crossing the German Ocean.

THE QUEEN'S SPEECH.—The great event of the year in telegraphy, the transmission of Her Most Gracious Majesty's speech, took place on the 4th instant. The speech, immediately on its delivery, was transmitted by the Electric and International Telegraph Company from its chief station in Telegraph-street to Vienna, Frankfort, Berlin, Rotterdam, &c. A portion of the speech, consisting of some 300 words, was sent to Hamburgh in 29 minutes. We had the opportunity of witnessing the transmission of the message to all the principal towns in the United Kingdom, and which we found to be at the rate of 35 words per minute. We are indebted to the obliging assistant-secretary of the Submarine Telegraph Company, Mr. Wichello, for the following information:—"The Queen's speech consisted of 900 words odd. Its transmission to Paris commenced at 1.22 p.m., and was finished at 1.36 p.m. Six wires were employed." Our readers will judge of the expedition with which the speech was transmitted from the following facts. Mr. Wichello was at the Treasury 2 minutes past 1 p.m., reached the chief office of the company at 1.22 p.m., and the speech was published in Paris in 14 minutes. The speech was also transmitted from London to Liverpool by the British and Irish Magnetic Telegraph Company on two of "Bright's" Bell Instruments in nine minutes. The speech contained 867 words, which gives an average of 48 words and a fraction of a word per minute, and when it is taken into consideration that the receiver writes for himself, the speed of transmission is truly marvellous. We are indebted to Mr. Walsh, the engineering superintendent, for the above interesting particulars.

THE TELEGRAPH AND THE BIRMINGHAM MEETING.—The lengthy report of the meeting at Birmingham on Tuesday evening, which appeared in the *Courier* of January 27, was transmitted from Birmingham to Manchester by the United Kingdom Electric Telegraph Company; and it is only right that the accuracy and despatch with which the task was accomplished should receive due acknowledgment. For the first time, probably, in the history of telegraphy, the operators at the instrument forwarded the report from dictation, the usual plan being to have a written or printed copy before them. On the present occasion, however, the whole of Mr. Bright's speech, which was given verbatim, was read to the operator from the short-hand writers' notes, and thus a saving of labour to the reporters and of time in the transmission of the report was effected. The entire report, extending over nearly five columns, was in Manchester by about half-past twelve o'clock, the meeting itself not having terminated until after ten.—*Manchester Courier*.

THE PERSIAN GULF CABLE.—News has been received this week from Colonel Stewart, Sir Charles Bright, and staff, who were still at Bombay, awaiting the arrival of the second vessel, the *Kirkman*, which was daily expected. All reported as well.

BONELLI'S TYPO-ELECTRIC TELEGRAPH.—A few of the leading members of the press, and of the scientific world, met last Wednesday at the offices of the company for the purpose of witnessing a series of special experiments on the working of the system. In addition to those which were so conclusive at the former meeting, some very interesting proofs were shown of the independence of loss to earth, and of metallic and intermittent contact, certainly to the surprise of those best versed in the science. A loss deflecting a galvanometer 75 degrees, and sufficient to make a dark band upon the paper, was completely neutralised by the beautiful system of currents invented by the talented Chevalier, and much interesting discussion took place as to the setting up of the type, the phenomena involved in the decomposition of the manganese, &c. The proof adduced and the explanations given were in each case most satisfactory. We most highly approve the open and candid spirit which dictates these meetings, and feel that they must tend to disabuse the minds of those who have been from various causes inclined to undervalue this beautiful and truly scientific invention. Among those who were present, and whose evident delight afforded the highest testimony to the merits of the system, we noticed Mr. Fleeming Jenkin, Mr. Charles Lamb Kenney, Mr. Dodd. Mr. Murphy, Mr. Williams, Lord Otho Fitzgerald, Mr. Le Neve Foster, Mr. Latimer Clarke, Mr. Woods, Mr. Turner, Mr. Fitzgerald, and Mr. Bateman.

THE PROPOSED NEW RAILWAYS AND TELEGRAPH PROPERTY.—The number of *notices* served upon the metropolitan telegraph companies by the solicitors of the new railway projects have been very numerous. We are informed that one company alone has been served with no less than forty of such *notices*, in which it is stated that, it being understood "you (the telegraph company) are interested in the property (telegraph wires) mentioned in the annexed schedule in the way in which the schedule states, that property, or some part of it, will, or may be required, for the purposes of the said Act, and it will either be traversed by the line of the proposed works in the manner mentioned in the schedule, or it may be required to be taken under the powers which will be applied for in the said Act of deviating from the line now laid down to the extent shown on the plans of the undertaking, &c." There is one project, if we are correctly informed, called the North and South London (*high level*) Junction Railway, which is likely in some parts of the town to vie in altitude with our aerial cables and wires.

PRIVATE TELEGRAPHY.—Most of our readers are aware that in London, as well as in many of the provincial towns of England, a system of connecting by telegraph merchants' offices with warehouses, mills, or other business premises, has been very generally adopted, and, we understand, has proved entirely satisfactory to the parties interested. Some short time ago, in scanning over our "exchanges," we noticed, in an article on "Private Telegraphs" in the *Telegraphic Journal*, that one merchant had been enabled, by its means, to dispense with the services of no less than four messengers, thus effecting a considerable saving in his annual outlay, without estimating the advantages derived from rapid communication. From a circular issued by the Magnetic Telegraph Company it appears that, for the sum of about £50, any one can become the proprietor of a complete telegraph, one mile in length, including two admirable instruments (one for each end), which the telegraph company will keep in working order for the further sum of £6 per annum. This, with say 5 per cent. on the purchase-money, will amount to £8 10s. per annum; so that, for a sum equal to the annual payment of £8 10s., a merchant can have complete telegraphic communication between business premises a mile distant. Longer distances do not add much to the expense, as the same number of instruments only is required. It appears to us (and the suggestion may be worth the consideration of the telegraph company) that a considerable saving of time might be effected by connecting merchants' offices with the central telegraphic station. The town council might certainly make use of this system of communication in connection with the fire brigade. Through the exertions of Sir John Gray and Captain Ingram, the chief of the fire brigade, Dublin, the town council of the Irish metropolis have had several stations connected by the Magnetic Telegraph Company for the use of the fire brigade. Property of considerable value has already been saved by the timely arrival of the engines, which would inevitably have been destroyed but for the rapidity with which information has been flashed from station to station. So fully convinced are the Dublin council of the necessity for prompt and immediate attention in such cases, that they have decided to have all their fire-engine stations fitted up with the necessary telegraph appliances. We are not aware whether the council defrays all the expense, but we should think that the insurance societies would be glad to co-operate in a matter which is so important to their interests.—*Belfast News-Letter*.

TELEGRAPH WIRES.—Although England for some time has monopolised the supply of telegraph wire, it appears now that Belgium is likely to prove a formidable rival in the future supply of the material. The State adjudication for wire for telegraph purposes was divided among various contractors; and we learn that one of the firms selected, having made within a period prescribed an abatement of 10 per cent., has obtained the delivery of the whole of the wire required. The fabrication is now in progress at one of the works of the Moselle district.

Telegraphic communication in India promises to be greatly improved. Mr. G. W. Kellner has lately been instituting an inquiry into the conduct of the electric telegraph department, which will lead to many important reforms in that much mismanaged branch of the public service. A system of false economy, extending even to the employment of common servants in the head office here, has completely destroyed the efficiency of the department. A new company also, called the Oriental Telegraph Company, has been organising, under the superintendence of Sir Charles Bright and Mr. Latimer Clark, a system of telegraph similar in its constitution to the Electric and International Company of England. Proceedings are now so far advanced, that the company is only waiting for a reply to a reference made to Sir Charles Wood. On the completion of the Persian Gulf submarine cable early next year, Sir Charles Bright and Mr. Latimer Clark will be ready to enter upon the operations of the Oriental Telegraph Company, commencing their Indian line from Kurrachee, and working towards Bombay and Calcutta.—Calcutta correspondent of the *Manchester Guardian.*

The Telegraph in Turkey.—The correspondent of the *Times* writing from Constantinople states that "the English Government have just sent out an agent to come to an understanding with the Turkish telegraph department as to the future working of the wires through Asiatic Turkey, which are soon to form one of the links in the Indian telegraph. It has been ascertained that, although the line to Bagdad has been successful, the posts are all rotting away, and will have to be changed. One of the principal difficulties is to be found in the impediments put in the way of the construction of the line from Bagdad to Bussorah by the Arabs. A party of English telegraphists was lately attacked near Bagdad, and all the telegraph material was carried away into the desert. On this section of the line it has been decided to use iron posts. These are a strong temptation to the Arabs, who use them as tent poles. The only way of obviating the difficulty is by coming to an arrangement with the Sheikhs of the different tribes, and granting a subsidy for protecting the line. Without that it is to be feared that there will be constant interruptions, especially as the Governor-General of Bagdad has no control whatever over these tribes. This arrangement has worked well at Mosul, where the line was exposed to the playful tricks of these marauding bands. At the outset the Government subsidized the chiefs, and now, far from injuring it, they contribute to keep it in good order. It is said that when the entire line is open for traffic to India, the Turkish line alone will yield upwards of £100,000 a-year, and with such prospects it is to be hoped that the Turks will give up such a portion of management to the English employés as may secure the proper working of the line—a success which their own department, as at present constituted, would find it difficult to achieve."

MISCELLANEA.

Mr. Culley in his new work gives the following list of insulators and conductors, the first on the list being the best insulator, and the last the best conductor:—

Ebonite.	Pure water.
Shellac.	Melting ice.
India-rubber.	Sea water.
Gutta-percha.	Saline solutions.
Resin.	Acids.
Sulphur.	Charcoal or coke.
Wax.	Mercury.
Glass.	Platinum.
Silk.	Lead.
Wool.	Iron.
Dry paper.	Tin.
Dry air.	Zinc.
Porcelain.	Gold.
Dry wood.	Silver.
Dry ice.	Copper (pure).
Stone.	

The Philosopher's Reward.—Whatever may be the difficulties of the task before us—and difficulties great and many there are—we may rest assured in the reflection that our reward is certain. No man ever followed the study of nature with honesty and diligence without an ample repayment of discovery. The particular object sought may not at that moment be attained. None can tell at the outset of an investigation where it may lead, or in what way it may terminate; but this is certain, that lead where it may, and terminate where it may, new, important, and interesting truths will have been met with, and the boundaries of human knowledge permanently enlarged. Disappointment in the study of nature is impossible, provided legitimate objects be alone pursued, and by the appointed means. When physical truth ceases to be admired and loved for its own beauty and excellence, and scientific discovery becomes merely valued as a source of personal reputation—as the road to wealth and power and earthly dignity, then, indeed, may the bitterness of disappointment be often felt, and jealousy and bickerings divide those who, beyond all men living, should be the first to set an example of unity and brotherhood, whose lives are habitually passed in the contemplation of the handwriting of God.

PRICES CURRENT OF INSULATING MATERIAL.

Gutta Percha, as imported.	
Genuine mixed, first and second qualities.	2/3 to 2/6 per lb.
Good re-boiled	1/7 to 1/10 „
India Rubber.	
Para, first quality	1/10 to 1/11 „
second „	1/7 to 1/8 „
third Negro-head	1/2 to 1/3 „
Java and Penang	1/4 to 1/6 „

TO CORRESPONDENTS.

As information respecting Improvements, Extension of Lines, and Progress of New Undertakings will at all times be most acceptable, we hope that our readers will kindly render us assistance in our efforts to establish a Journal worthy in all respects of the great interest it seeks to represent, by furnishing us with brief notices of events and occurrences in connection with Telegraphy.

Communications intended for publication must be authenticated by the names and addresses of the writers; not neccessarily for insertion.

Letters relating to Advertisements are to be addressed to the Publishers. All other letters and communications to be addressed to the Editor of the *Telegraphic Journal,* 5, Suffolk-lane, Cannon-street, London, E.C.

The *Telegraphic Journal* can be had of Messrs. Smith & Co., Strand; Messrs. Dawson & Co., Cannon-street West; Messrs. Kent & Co., Paternoster-row, London. Messrs. Heywood & Co., Manchester; at the various railway stations; and of all news-agents, &c., &c.; or it can be supplied, if preferred, direct from the Office on the following terms (paid in advance):—

	s.	d.
Quarterly	4	4
Half-yearly	8	8
Yearly	17	4

TO ADVERTISERS.

The *Telegraphic Journal* is the most effective medium for inventors, patentees, contractors, manufacturers of insulating materials and electrical apparatus to submit their various specialities to the consideration of secretaries and managers of telegraph or railway companies, and other persons engaged in electrical and telegraphic pursuits.

Clerks, assistants, manipulators, and instrument makers, seeking employment, &c., will find the *Telegraphic Journal* a ready means of making known their requirements.

Advertisements must be delivered to ensure insertion before Seven o'Clock on Thursday evening in each week. The charges for Advertisements are—

	£.	s.	d.
Whole page	4	4	0
Half ditto	2	10	0
Quarter ditto	1	7	6
Four lines and under (single column)	0	3	0

Single Advertisements from the country must be accompanied with stamps in payment.

THE ORAN AND CARTHAGENA DEEP SEA CABLE.

The accident to the above cable, as announced in our last number, has cast a gloom over the spirit of enterprise so far as it is directed to the development of deep sea telegraphy, and which is to some extent aggravated by the fact that the great commercial interests of the country are smarting under the inconvenience and loss experienced by the protracted silence of the Malta and Alexandria cable.

The French telegraph screw steamer, *Le Dix Decembre*, left the Thames, on the 16th December, with 130 knots of cable on board, destined to connect the Spanish town, Carthagena, with Oran, in the north-west of France. With the exception of a few days' delay, in consequence of unpropitious weather, the vessel arrived safely at its destination, and on the 28th of January the operation of laying the cable was commenced; and it appears, from the report of Mr. Siemens, that the operation progressed to his entire satisfaction and the other engineers on board for about one third of the way, when the cable suddenly broke in a place where the hempen strands appeared to have been unduly weakened by some chemical agency; the depth, at the time, being about 2,700 metres. We have already, in a previous number, referred to this cable as being of novel construction; its outer covering, which formed its strength, consists of a double layer of hemp strings, or lines (of the strongest materials, saturated, we believe, with Stockholm tar), laid spirally under considerable tension, the twist of the two layers running in opposite directions, and it was finally covered by a flexible copper or brass sheathing composed of bands of sheet copper or brass, put on spirally under the influence of great pressure, and with each succeeding turn overlapping the preceding, resembling, to some extent, the scales of a fish. The conductor was enveloped, as usual, in several coatings of gutta-percha and Chatterton's compound. The novelty of construction, and of the means adopted for paying-out the cable had, for some time, given rise to much speculative discussion among telegraph engineers, and others interested in the progress of deep-sea telegraphy, as to the amount of success which might be expected in an attempt to submerge a cable in great depths, under conditions of avowed novelty and by no means devoid of ingenuity. If the cause of failure is correctly ascertained to have resulted from some chemical agency impairing the strength of the hempen cords, while in the course of transit, the adaptability of the cable for the purpose it was intended, or of the machinery employed on the occasion, cannot justly be doubted, as some 40 knots of the cable were successfully submerged in great depths; and so convinced were the French and Spanish engineers on board of the superior merits of the cable, and of the machinery, that they recommended the same for future adoption. It is not our wish, or inclination, to aggravate or embitter, by any observations of our own, the pain or the disappointment already experienced by those more immediately concerned, but rather to unite, with an enlightened and considerate community, in an expression of sympathy for those whose reverses are after all, we trust, but steps which ultimately will lead to success and triumph.

We would here impress upon the minds of our readers the fact, that the practicability of deep sea telegraphy is not in the least affected by the late accident. We believe, as firmly as ever, "that a well-insulated cable properly protected, of suitable specific gravity, made with care, and tested under water throughout its progress with the best known apparatus, and paid into the ocean with the most improved machinery, possesses every prospect of not only being successful in the first instance, but may reasonably be relied on to continue in an efficient state for the transmission of signals."

In order, however, to remove the doubts which possess the public mind, we trust that the portion of the Oran and Carthagena cable, in which the deterioration had taken place in the tensile strength of the hemp, will be subjected to the severest tests, so as to ascertain the true cause thereof, and, if possible, to arrange some means of determining the uniformity of strength before the cable is coiled for submersion, as it is strongly suspected that other cables have had their "weak points," only to be discovered, when too late, in the operation of paying out into the ocean.

As we were on the point of concluding our observations intelligence reached us that the cause of failure was at a splice made at the contractors' factory during the shipment, and that the hemp at that particular place was, on investigation, found discoloured and damaged by some chemical agency, as acid, which, by some unlucky accident, must have had access to the place while the joint was being made. In all other parts of the cable the hemp is represented as being in as good and unchanged condition as ever.

HOW TO POPULARISE TELEGRAPHY.

Nothing would appear to be more foreign to a journal of this nature than to assume the right of dictating to the large telegraph companies the course they should pursue to bring before the public notice the value of "what they have to sell." As, however, the welfare of telegraphy, and the success of our vast telegraphic system will admit of a practical suggestion, Why, we should like to ask,—why is it that we know so little of the changes that take place in telegraphic arrangements? We allude more especially to the reduction in tariffs, and other advantages so frequently placed at the public disposal, if they only knew of them. While railway companies and insurance companies lose no opportunity of bringing forward, with every means of publicity in their power, the benefits of their excursion trains on the one hand, and of life assurance generally on the other, the telegraph companies prefer to hide their most wonderful and valuable commodities from all public gaze. They apparently make no effort to send forth information, but expect the world at large to ascertain these full particulars which may, no doubt, "be obtained at any of the company's principal stations."

It is not alone in the metropolis, but in all the provincial towns, that the custom of the telegraph companies is confined to a very select circle. Ninety-nine people out of a hundred will scarcely be aware that they can telegraph at all; certainly not that, for the sum of one shilling, they can waft their wishes 200 miles in less than a minute. The system of private telegraphs is one step towards bringing the public system more generally into use, and a reduction in the public tariff has been naturally followed by a large increase in the number of tele-

grams, still there must be a large class who are not included amongst the telegraphers.

It is not our wish to see any part of the companies' revenue wasted in superfluous advertising, but it must surely be apparent to the directors of all telegraph undertakings that publicity is calculated to bring an exceedingly large increase to their present income. It would be interesting to know what per centage of the population is found to use the telegraph systems.

As an instance of the fallacy that, no doubt, is widely spread, a medical man, of high repute, sent off his man-servant with a short message to Paris, and gave him *two sovereigns* to pay for it, desiring, if that was not enough, that they would let the message go forward, and his servant should return immediately with any balance due. He was perfectly astonished to find that the cash brought back was thirty-five shillings; that, in fact, his message had only cost him *five shillings*, while for the amount he had supplied his message might have been sent to St. Petersburg, and an answer received. Now this, we feel sure, is not as it should be. The electric telegraph is for an emergency in private life, as well as for a regular service to the merchant, or broker, and it is curtailing its boundless sphere of usefulness to allow it to be viewed as a means only to be used for and by the wealthy classes. Who is likely to make his first attempt at a telegram, if he thinks the cost will be half-a-week's income? "I didn't know that I could telegraph," says the working man; "had I known that it would only cost ninepence, I would have telegraphed at once for my wife to see her dying child." He knows he can have eight hours by the sea-side for half-a-crown, but continues to believe that that wondrous electricity is kept in bottles, like old wine, the taste of which is denied to him.

Day by day, as we take up our morning paper, everything is brought before us in full blast of letter-press, *except* the telegraph service.

Granted that placards are erected at the telegraph offices; granted that all these blessings may be had; and granted too that the public are served well and cheaply: but then the people are ignorant of this, and while that continues the service must be more or less exclusive. We wish to remark, however, that one step has recently been taken by the London District Telegraph Company, in distributing widely an almanack and list of stations, in pocket-book form. This is a right step. It would be difficult to send abroad too many; they will simply represent good seed sown on ground that is calculated to reward the sower with a plentiful harvest. The large sheet almanack distributed by the Electric Company is also a good and useful counting-house reference, and it is usual to give away large quantities of tariff sheets; these, however, mostly find their way to those accustomed to telegraph regularly. It is, we think, worthy of consideration whether it would not be to the advantage of the different companies to keep their distinguishing merits well before the public, in those daily and weekly journals that, in their advertising columns, always contain so much valuable information, and which are read with interest by the intelligent portion of the community.

Progress of Canada.—Any one who cares to examine the progress of Canada during the last 25 years will be satisfied, we venture to say, that the future of that country is secure beyond all precedent. In 1825 Canada had 581,920 inhabitants; in 1851 these numbers had trebled, or reached 1,842,265; and in 1861 they had quadrupled, being 2,506,755. At this time the population of Canada approaches three millions. On the roads, railroads, and canals of the province sixty million of dollars have been expended by the Government, apart from the advances made by the English capitalists. There are now 1,800 miles of railway and 3,422 miles of electric telegraph completed. The number of letters passing through nearly 2,000 post-offices were upwards of 9,000,000 in 1860. These facts show that the civilisation of the country is progressive and in strict accordance with the spirit of the times.

SUBMARINE CABLES.

II.

In our last number we quoted at some length the opinions of telegraph engineers and others upon the subject of corrosion, which has so materially affected the permanency of submarine cables—more especially when submerged in shallow water, as is the case with most of our present cables. Although this cause of danger had been foreseen in time to provide against its recurrence in the expensive line between Malta and Alexandria, still no precautionary measures were adopted, and it is to be feared that in this instance, as observed by Mr. C. W. Siemens, F.R.S., that "so far from the iron being an element of strength," it will become "an element of actual weakness when the cable requires to be raised for repairs." Indeed, we find that Sir Charles Bright, at the discussion upon Mr. Preece's paper on Submarine Cables, recommended that means should be adopted to protect the said cable from corrosion. It will be interesting to some of our readers who have not had the opportunity of reading the ponderous "Blue Book," containing the result of the investigations of the late Submarine Telegraph Committee, to learn of the attempts made by some of our ingenious inventors and enterprising manufacturers to contrive cables with a view of avoiding the above serious effect of corrosion, &c.

Mr. Thomas Allan proposes a cable of a novel and ingenious construction, dispensing altogether with an external iron coating. The cable consists of a copper conducting wire of a large size, covered spirally with a number of steel wires of gauge 25, and coated with an insulating material of the required thickness, the whole finished in a covering of plaited jute, &c. One of these cables was weighted to 1,787 lbs., and the extension before removing the weights did not exceed ·67 per cent. The permanent extension upon a length of 20 feet was = ·234 per cent., the return = ·443 per cent., and the breaking strain equal to 4,698 fathoms. Other specimens had breaking strains of 6,348 and 7,484 fathoms respectively. Mr. Allan produces a cable which certainly possesses several important advantages besides that of having its element of strength completely protected from the corrosive influence of water; it is small in bulk, of light specific gravity, great strength, and not liable to kink.

Mr. Godefroy has contrived a cable in which the conducting copper wire is insulated in either gutta-percha or india-rubber, outside of which, for strength, a number of steel wires are placed in close parallel lines, the whole being afterwards insulated or enveloped with patent cocoa-nut gutta-percha, and again with two coatings of india-rubber waterproof canvas. One of such cables was weighted to 1,787 lbs.; the extension before removing the weight was = ·520 per cent., the permanent extension = ·182 per cent., and the return = ·338 per cent. This description of cable, like that of Mr. Allan's, is exclusively intended for deep-sea lines.

Messrs. Hall & Well's cable consists of a copper conducting wire covered with india-rubber, closely served with tarred thin yarns, a number of longitudinal hemp lines and longitudinal steel wires braided together, with strands of hemp saturated with best Stockholm tar. One of these cables was weighted to 1,787 lbs.; the extension before removing the weight was = ·416 per cent., the permanent extension after removing the weight = ·208 per cent., and the return = ·208 per cent. This kind of cable is free from liability to kink, has a light specific gravity, combined with great strength. The breaking strain is from 5,000 to 11,000 fathoms.

Mr. Sinnock describes his cable as follows:—Core of strands of copper wire covered with gutta-percha served with waterproof tape, then eleven longitudinal thick marlin lines, each consisting of nine tarred yarns served spirally with hempen string, the whole served with two turned iron wires and three tarred strings. One of his cables was weighted to 1,787 lbs.; the extension before removing the weight was = 1·664 per cent., the permanent extension was = ·933 per cent., and the return = ·728 per cent. Breaking strain equivalent to 2,855 fathoms. This is a compact and exceedingly well manufactured cable.

Messrs. Silver & Co. produce a cable consisting of a copper conductor insulated with india-rubber, then served with tarred yarn, outside of which steel wires in close parallel lines, and covered with plaited hemp saturated with a peculiar compound. The breaking strain equivalent to 2,675 fathoms. Messrs. Silver & Co. exhibited several specimens at the International Exhibition, differing in some respect from the above, and which appear to us to be well adapted for the purpose of ocean telegraphy.

Mr. De Bergue's are, perhaps, the most perfect hempen-covered cables hitherto contrived. Very small in bulk, light specific gravity, and great strength. A cable having an external diameter of $\frac{8}{16}$ths of an inch, breaking strain exceeded 16,000 fathoms. The following is a description of the cable:—A core of seven strands of copper wire covered with gutta-percha, next seventeen longitudinal tarred hempen lines served with similar sized cord of hemp.

THE PROTECTION OF SHIPS' BOTTOMS BY ELECTRICITY.

IT may be truly said that maritime supremacy, and the successful development of mercantile enterprise, hinge upon the attainment of the maximum of speed. Yet, notwithstanding the thousand and one paints, varnishes, and compositions, which have been consecutively introduced of late years to compass this desirable object, it still remains a desideratum. The clean hulls of vessels as they emerge from port, are still rapidly encrusted with barnacles, shell-fish, and sea-weed, to the great detriment of their sailing or steaming properties, and the creation of a vast additional expense in the increased length of time occupied in the voyage. To show the magnitude of the evil here referred to, it not unfrequently occurs, that a steam ship, leaving port with an initial speed of eleven and a-half knots an hour, has that speed reduced, in three or four weeks, to eight knots an hour, by the adhesion of barnacles, whose presence and neutralizing force might be extinguished, by the employment of proper means. It was formerly thought that this object might be accomplished by poison, and hence a variety of toxicological compounds were from time to time incorporated with the *protective* composition; but these have been found of no avail, for barnacles and adherent shell-fish possess the power of producing and using with instinctive judgment a most powerful cement, capable of speedy induration; and no sooner do they begin to feel the evil effects of the poison in question, than they quickly interpose an impenetrable shield of hard calcareous matter between themselves and the poisoned surface of the ship's hull.

The only power that can be effectually employed in their destruction and detachment, must be at once prompt, searching, diffusive and inevitable. Such a power is electricity. Its influence is great over all organised structures, particularly over the nervous and muscular systems of animals; and of all the divisions of the animal kingdom, fishes are the most keenly susceptible of its overpowering influence. This arises, no doubt, in great part from the fact, that the entire surface of their bodies is generally in perfect electric contact with a good fluid conductor, which surrounds them in immense volume.

Mr. Isham Baggs, who was for many years connected with the Polytechnic Institution of London, and whose scientific applications of electricity to various purposes have earned for him a just renown, has published a very interesting paper on "The fouling of ships' bottoms prevented by electricity," wherein he shows that the various compositions generally employed for this purpose fail to effect the desired object, and in which he demonstrates the power which can be exerted with proper electrical appliances upon marine animals and plants. Mr. Baggs' experiments and opinions are worthy the consideration of all persons engaged in practical navigation; and we have pleasure in giving publicity to the results of some of his interesting researches. Referring to the cirrhipediæ (of which the common duck barnacle may be taken as a specimen), a sub-family of the class *crustaceæ*, and to whose presence the fouling of the hulls of vessels is in a great measure to be attributed, he says:—

"I obtained a large and close cluster of barnacles, the peduncles being about a foot long, and the whole weighing in the aggregate some thirty to forty pounds. The animals were evidently vigorous and healthy. I placed them in water between the two poles of a battery, lying a few feet apart. I scarcely anticipated any very speedy result, in consequence of the obstruction offered by the cement; but in less than half a minute, the apical portion of the shells opened, the plumose cirrhi protruded, the peduncles gradually lost their firm fleshy appearance, and shrunk both in length and diameter to half their original size, and notwithstanding the inferior conducting power of the half-dry piece of timber to which they were attached, the whole of the animals were effectually killed. Anxious to probe this interesting question still further, and to ascertain if the more completely armed crustaceans were capable of offering any serious resistance to the electric discharge, I took a young and lively crab, in size about sufficient for a moderate man's supper, and placed this in the water, as I had done the barnacles. The very moment I turned the electricity on, the question of defence or no defence was answered, for the animal gave a start so indescribably sudden, that nothing but electricity could have produced it. The creature stood motionless—I broke contact immediately—when the power over the muscles terminating, the crab ran off, faster, perhaps, than ever crab ran before. This convinces me that if even a momentary shock be distributed over a ship's bilge, whatever animals may be there, if only possessed of the faculty of locomotion, as are the larvæ of barnacles, they will quickly and certainly make good their escape to a more placid and genial atmosphere, without waiting for any second notice.

"The attachment and vegetation of marine plants upon the hulls of ships is mainly due in my opinion, and still more in the opinion of practical navigators, to the entangling and rugged surface of adhesion offered to such productions by the accumulation of barnacles and shell-fish. If therefore we prevent the formation of this rugged calcareous surface, by the destruction of the animals producing it—as can most certainly be effected by the electric discharge—we should then also expect to get rid of the marine vegetation which is its consequence; and there can be no doubt such will prove to be actually the result wherever electricity is employed. But let us, for the sake of argument, assume the contrary. Let us suppose that sea-weed is capable of effecting a firm and secure footing upon the otherwise clean surface of an iron vessel, or of a vessel sheathed with copper, or Muntz's metal. The feeble adhesion of the organized material, bound together by vitality, might possibly prevent it from being torn asunder until it was traversed by the electric shock, and then the vitality and cohesion of the mass would give way together; for the effect of life in any organized body is to bind the particles of that body into a concerted whole; the effect of electricity, when in sufficient strength, is to destroy the cohesive polarity, and to *disunite* them. These are only different expressions for well-known phenomena attending life and death, in plants and animals, for the effect is the same in both. Life is strength: death is weakness and decomposition. Now it is a well-known fact, that the passage of shocks through living plants immediately destroys their vitality; and it is further known that a very small quantity of electricity is sufficient for this purpose. A small Leyden jar, containing not more than six or eight inches of coated surface, is sufficient, if sent through the stem of a balsam, instantly to destroy it."

It has long been the subject of anxious study and careful experiment on the part of our scientific men to determine the most useful applications of the electric fluid; and we must certainly congratulate Mr. Baggs upon his marvellous discoveries and ingenious appliances. We have endeavoured in a brief way to show how by means of electricity, the fouling of ships' bottoms, one of the most serious drawbacks to that essential element in navigation—speed—may be easily and effectually removed. The simple mechanical contrivances whereby this important object is accomplished, and which have been patented by Mr. Baggs, may be seen by those who have either the business or the curiosity to enquire. The present application is only another small but a most useful instalment of the benefits which electricity will eventually confer upon mankind—benefits whose ultimate tendency is beyond the scope of human ken, and whose ameliorative power and greatness—

"Lie yet within the unread events of time."

TO ERECT A LINE OF TELEGRAPH.

(*Continued from p.* 52.)

THE Telegraph Act, 1863, being 26 & 27 Vict., cap. 112, is so framed, that it is feared, in offering it to our readers, in a condensed form, we should but mutilate it, without giving its full value. It has already been alluded to as full of information, as well as law, and we will, therefore, only mention specially those sections that provide for certain Forms of Notice or Consent, for the sake of giving the forms themselves, in which they should be rendered.

It is necessary that every notice should be in writing, or print, or partly in writing, and partly in print, and such notice may be given to or by the secretary, clerk, surveyor, or other officer, whether of the telegraph company, or of the body having charge or contract of the street, road, drainage, &c.

Section 8 provides for the security of gas and water mains. Before the position of such pipes is altered, twenty-four hours' notice is to be given to the body to whom such pipe belongs, of the intention to interfere with it.

This notice should be given in the following form:—

To &c., &c.

I HEREBY GIVE YOU NOTICE, that under and by virtue of the power and authority given to the *British Electric* Telegraph Company, by "*The*

British Electric Telegraph Company's Act, 1853," 16 & 17 *Vict., cap.* clix., and by the Telegraph Act, 1863, 26 & 27 Vict., cap. cxii., the said *British Electric* Telegraph Company will proceed, at *three* o'clock in the *fore*noon, on the *fourth* day of *February,* 1864, to open and break up the Road or Way called *Acton Bottom* Road, and leading from *London* to *Uxbridge,* or so much thereof as may be necessary for the purpose of *constructing* (or *altering*) their Telegraphs; and that the said *British Electric* Telegraph Company will alter the position of your pipe or pipes, be they mains or branches.

Dated this day of 1864.

(Signed)
For the *British Electric* Telegraph Company.

Section 10 requires that due notice shall be given before proceeding with the placing of a telegraph under a street or public road. Except in cases of emergency, ten days' notice of underground work, and five days' notice of aboveground work, must be given.

The above form may, in such case, be used, but for underground work, it will be necessary to add:—

"The depth of the underground line will be *twenty-four inches;* the course will be *direct from London to Uxbridge,* and the position throughout will be *in the centre of the pathway.*"

Section 23 provides for the erection of aboveground lines; and *after* the consent of the street or road authorities has been obtained, the following notice has then to be advertised, and publicly delivered at every dwelling-house on the route proposed to be taken, at least twenty-one days before proceeding with the work:—

UNIVERSAL PRIVATE TELEGRAPH COMPANY.

Incorporated by Special Act of Parliament, 1861.

Pursuant to the Provisions of an Act of Parliament made and passed in the Twenty-fourth Year of the Reign of Her present Majesty Queen Victoria, entitled the "*Universal Private Telegraph Act,*" 24 *Vict., cap.* 61, and also of an Act of Parliament made and passed in the Twenty-seventh Year of the Reign of Her present Majesty Queen Victoria, entitled the "Telegraph Act, 1863," 26 & 27 Vict., cap. 112.

Notice is hereby given, that the *Universal Private Telegraph Company,* having obtained the consent of the body having the control of the street or road hereunder mentioned, and of the other persons whose consent is required, by their own, and the said Act respectively, intend to construct a line of Telegraph along the road or highway leading from *Littleborough to Rochdale,* and for that purpose to set up and erect poles and other apparatus connected therewith, by the side of, over, along, or across the said road or highway, in accordance with the powers granted by the said Acts respectively, some or one of them.

One Form of Consent will serve to carry out all the intentions of the Act; this should bear a sixpenny stamp, and it is usual to have two copies signed and exchanged between the two contracting parties.

Agreement made this *fourth* day of *February,* One thousand eight hundred and sixty *four,* between *John Williams, Manor House, Maidenhead,* in the County of *Berkshire, Farmer,* of the one part, and *Frederick Jones,* Secretary of and acting for and on behalf of the Telegraph Company, hereafter called the Telegraph Company, of the other part.

The said John Williams permits the said Telegraph Company to carry their Telegraph across his property, situated at Pinkney's Green, in the County of Berkshire, and to affix their poles and wires to the said property, and to allow the said Company, their servants, and agents, to enter upon the said property, from time to time, as there may be occasion, for the purpose of repairing, altering, and removing the said Telegraph, the said Company hereby agreeing to pay the said John Williams the sum of per annum, for so long as they shall continue to use these privileges, the said sum to be paid in advance, and the first payment to be made on the *twenty-fifth day of March,* One thousand eight hundred and sixty four. And, further, the said Company undertakes to remove the said Telegraph Poles and Wires from off the said property within six calendar months after the said John Williams shall have given them a written notice, requiring them so to do.

As witness our hands,

(L.S.)

(L.S.)

THE INTERNATIONAL EXHIBITION, 1862.

(*Continued from p.* 67.)

J. Rogers (United Kingdom, 2,950), exhibits specimens of insulated wire with hempen cords ingeniously plaited round the core, so as to give considerable strength and lateral protection combined with great flexibility. The rope, moreover, is free from any liability to kink. This form of cable seems well suited for some purposes; for instance, it might be used in connection with chronoscopes, electric targets, &c., where short lengths of insulated wire have to be frequently moved from place to place, but it is unsuited for submarine cables. Although strong, it admits of considerable extension, and any accidental strain on the cable might stretch the core.

The teredo, which has been already mentioned as almost invariably attacking unprotected hemp, would very shortly strip the core of the strengthening cords, leaving a bare core which could never be recovered, and might probably be injured by the animals; the hemp, by fostering these animals, instead of a protection, may become a source of danger.

Wells & Hall, H. M. (United Kingdom, 2,988), exhibits a deep-sea cable, in which the outside wires lie parallel to the core. They are held in their place by an ingenious plaiting of hemp, which entirely surrounds each wire and gives the whole cable the appearance of being covered with hemp alone. This cable will bear a great strain without stretching; it is not liable to kink, and could be easily laid in almost any depth; it would not be, however, more permanent than the Toulon-Algiers form already described.

C. Duncan (United Kingdom, 2,896) exhibits specimens, in which the usual iron wires are replaced by ratan canes; it is stated that a cable of this form one inch in diameter will bear upwards of two tons, and weigh less than three-quarters of a ton per mile. It is a comparatively easy matter to design a cable which can be safely laid in any necessary depth, without having recourse to short pieces of cane as a covering. The difficulty is to find a permanent material, which shall retain its strength and continue to afford protection after the cable is laid. Mr. Duncan, from experience obtained with ratan ropes in China, believes that cane would be found more permanent than iron wires. The writer cannot share this opinion, but owns that he is ignorant of the special properties of cane. Mr. Duncan states that he has successfully overcome the serious difficulties of the manufacture.

E. B. Sharpe (United Kingdom 2,956) exhibits specimens of submarine telegraph cables, in which the usual outer spiral, or rather helical iron sheathing, is replaced by a sheath of straight wires kept in their place by a serving of hemp or iron, or both combined. This invention is designed to meet the following supposed defect. It is argued, that as an open spiral or rather helix of a single wire elongates with the smallest strain, so a cable covered with a series of these helices must elongate in a similar manner, to the great detriment of the contained core. In this age, when experiment is so highly esteemed, it seems incredible that this statement should have received the support and credence which has been accorded to it even in some scientific journals. The fallacy becomes almost tangible when a specimen of the usual cable is simply handled; and direct experiment shows that a well laid-up cable of the usual form hardly stretches more than a solid bar of iron under corresponding strain. Thus, experiment made for the Government by Messrs. Gisborne & Forde, and Mr. C. Siemens, show that the Red Sea cable, covered with eighteen wires of about 0·74 in. diameter, bore from 70 to 80 cwt., and stretched from 0·56 to 1 per cent. before breaking, while single wires a little larger in diameter bore from 4 to 4½ cwt. and stretched from 0·4 to 0·52 per cent. before breaking. It will readily be seen that the open coil or helix, extends by diminishing in diameter, whereas the wires of a cable put up one against the other, forming a complete circle, the diameter of which cannot diminish unless each circular iron wire could be squeezed oval—in fact, each wire may looked on as a segment of an arch defying any compression applied equally on all sides. The slight extra extension observed in the cable as compared with the solid rod, is due to a slight diminution of diameter produced by the more perfect closing of the wires under the strain; the better the rope is laid-up, the less this will be. No lateral compression, nor longitudinal strain of any consequence ever comes on the soft extensible core of the cable; indeed, the great merit of the present iron-sheathed cable is the perfect protection afforded to the core against mechanical injury.

Mr. Sharpe's bundle of straight wires could be far more easily squeezed out of shape than the usual rope; it would be less flexible, and would stand far less of the hard usage to which cables are necessarily subjected: it would be less liable to kink, but the danger from this cause has been enormously exaggerated.

4. *Paying-out Apparatus.*

Mr. Sharpe also exhibits a model of some machinery for paying-out cables. This model more properly belongs to Class VIII.; and as the opinion formed of it was not very favourable, the writer omits, at Mr. Sharpe's request, the description he had prepared.

5. *Insulating Materials for Submarine Cables.*

Gutta-percha and india-rubber are the only two materials which have hitherto been used for the insulation of submarine conducting wires.

S. W. Silver & Co., M. (United Kingdom, 2,960), exhibit specimens of wire insulated with india-rubber; and one specimen a mile in length, formed part of a core manufactured in 1860, and favourably reported on by the Committee of the Board of Trade on Submarine Cables. They also show specimens of a rope about ¾ of an inch diameter, containing fifty insulated wires, and used with success by the Universal Private Telegraph Company, for over-house work in London and elsewhere. Messrs. Silver cover their wire by lapping a series of tapes round and round the copper wire, and they consolidate the mass by subjecting it to the temperature of boiling water for about half an hour.

Wells & Hall, H. M. (United Kingdom, 2,988), also exhibit various specimens of wire insulated with india-rubber, one of which represents the core of a short cable about to be laid in the Persian Gulf.

Siemens, Halske, & Co., M. (United Kingdom, 2,959), exhibit a wire insulated in the first instance by india-rubber, and then covered with gutta-percha. Their india-rubber is applied very ingeniously by a machine exhibited in Class VII.

The process depends for its success on the property of two freshly-cut surfaces of india-rubber to adhere when brought together under considerable pressure. Two long tapes of rubber are laid along the two opposite sides of the conducting wire; their edges are cut and immediately afterwards they are pressed round the copper wire by rollers; the edges join under the pressure so as to make a continuous cylindrical cover with two straight longitudinal joints running the whole length of the wire. Two or more of these coatings are applied with the joints in different planes, and the whole is then covered with gutta-percha by the usual die process. By this plan the india-rubber is neither heated nor stretched, and the spiral channels, which are to be feared in the lapping process, are altogether avoided.

India-rubber tapes, when first applied to the insulation of wire, were cemented by means of solvents; but the covering thus made decayed very rapidly. Heat was next adopted to unite the mass, but many specimens so prepared are found under many circumstances to become sacky, *i e.*, to turn into a sticky semi-fluid substance, not only outside, where exposed to the air, but inside next the copper. The cause of this change is by no means well understood. Some say it is due to the process of mastication, by which the india-rubber is prepared before being cut into tapes; others, that the heat used to cement the various layers is to blame; others, that the tension of the tapes while they are being wound round the wire alters the structure of the material; some look for the source of danger in some chemical action on the copper with which the india-rubber is in contact, and it is probable that tinning or varnishing the copper does to some extent prevent the change described. Chemical analysis has hitherto given but little clue to the nature of the change. Messrs. Siemens' india-rubber applied cold, without tension, so far as the writer knows, does not turn sticky; but unless covered with gutta-percha, the longitudinal joints are liable after a time to open.

W. Hooper, H.M. (United Kingdom, 2,915), exhibits specimens of a manufacture, by which it appears that the "tackiness" of the india-rubber is prevented. He first coats his copper with the usual lapping of india-rubber tape; he then covers this india-rubber with what he calls a separator, which may consist of tinfoil, iron wires, oxide of zinc, &c. Outside this he applies india-rubber, mixed in various proportions with sulphur. He then subjects the whole for some time to a temperature sufficiently high to vulcanise the outside covering. This temperature would reduce unprotected pure india-rubber to a mere semi-fluid, useless mass, but when protected as described, the inner india-rubber is cemented into a compact solid mass, retaining no trace of the original subdivisions or joints. The use of the separator is to prevent the sulphur from affecting the inner india-rubber to such an extent as to injure the copper, or, perhaps, to impair the insulating properties of the material.

Mr. Hooper does not look on the outer hard or soft vulcanised india-rubber as of much use in the insulation, when wires intended to give strength are used as the separator. It is to be regretted that this process should hitherto have been applied apparently only to very short specimens. It would appear difficult to make joints, as the condition of the outer covering must depend on maintaining exactly the right temperature for exactly the right time; and the inner coating cannot be manufactured without the outer coating. Mr. Hooper claims to have overcome this difficulty. It remains to be seen in practice whether, in overcoming one defect, Mr. Hooper may not have introduced fresh dangers, arising from the very complication of the process.

The Gutta-Percha Company, M. (United Kingdom, 3,000), exhibit specimens of the cores, or insulated wires, which they have supplied for fifty-one submarine cables during the past eleven years. Some of these have failed, and undoubtedly some of the failures have been due to bad insulation caused by defective manufacture, or improper treatment after manufacture.

Much skill is required to make a good joint between two distinct lengths of covered wire or core. The copper conductors of the two lengths are soldered together, and the gutta-percha covering of the bare joint is applied by hand. If the gutta-percha used for this covering is overheated or dirtied, or in any way unskilfully manipulated, the adhesion between the new and old materials is imperfect, and the joint, although it looks well and tests well at first, gradually opens so as to admit the water to the copper. This fault is enlarged by the action of the voltaic current. The copper is gradually eaten away; it finally separates altogether, and the signals can be no longer transmitted. Joints made at leisure by experienced workmen are as sound as any other part of the core; but the apparent ease of the process sometimes tempts novices to try their hands with fatal results; and undue haste at sea sometimes causes the work to be slurred. There is no reason to suppose that fewer joints would be required with india-rubber covered wires, or that they could be made with less risk of failure. On the contrary, solvents are sometimes used to make these joints, although their use has been abandoned for the general manufacture.

Numerous air-holes have been found in some gutta-percha cores. These cavities, under pressure, become filled with water, and sometimes, under the action of powerful currents, are developed into faults or holes, which establish a communication between the conductor and the sea. It is believed that the Gutta-Percha Company have in the later cables entirely avoided this defect.

Gutta-percha becomes plastic at temperatures slightly exceeding 110 deg. Fah., and some injuries have occurred from this cause; it is also a soft substance, which can easily be cut or otherwise mechanically injured. The two first-named defects are practical defects, and would never have been discovered if only short specimens had been made.

The merits of the material are so great that it can well bear to have its imperfections disclosed. More than 20,000 miles of wire insulated with gutta-percha have now been submerged; many hundreds of miles have been again pulled up after remaining submerged in different parts of the world for several years in shallow water, and in depths of 1,000 and 1,500 fathoms, but not one yard of the recovered cable has been found to have decayed. Gutta-percha cores can be bent, kinked, and even knotted, without receiving any injury of importance, and the electrical qualities of the material, always valuable, have lately been wonderfully improved by the manufacturers. To show the perfection to which the manufacture has been brought in a mechanical point of view, the Gutta-Percha Company exhibit some copper wire $\frac{1}{350}$th of an inch in diameter, covered with gutta-percha to $\frac{1}{16}$th of an inch diameter. This very fine covered wire weighs about 1 lb. per knot. They also exhibit a sheet measuring 12 feet by 10 feet, and weighing 30 grains per square foot.

The cores of almost all the cables named in table C were supplied by this company.

The Board of Trade Committee found that the insulation obtained from india-rubber prepared by Messrs. Silver was twice as good as that given by the usual specimens of gutta-percha—but thereupon

a specimen of gutta-percha was produced which equalled the india-rubber. Tests recently made by the writer seem to show that gutta-percha, as now prepared, is the better insulator of the two. The word insulation is here used in the limited sense of high electrical resistance. A material (for instance, glass) might be spoken of as the best insulator, without its by any means following that it was the best material for the insulation of submarine wires.

The annexed table D gives the data on which the above statement is founded. The headings of all the columns but the last sufficiently explain their meaning. The last column contains the specific resistance of the material insulating each cable; it would be constant if all the materials had been alike. The specific resistance is the resistance of one cubic foot to conduction between two opposite faces. The higher the figure the better the insulator. It will be seen that Messrs. Silver's material has twice the specific resistance of that used for the Red Sea cable, and that the gutta-percha of the Malta-Alexandria cable has nearly twice the resistance of Messrs. Silver's india-rubber.

TABLE D.

NAME OF CABLE TESTED.	Copper Conductor.				Insulator.				Approximate ratio $\frac{D}{d}$ *	$\log_{\epsilon} \frac{D}{d}$	Insulation Resistance per knot, R, at 60° Fah. in Siemens' large mercury units after electrification for one minute.	Specific Resistance $\frac{2\pi R L}{\log_{\epsilon} \frac{D}{d}}$ (L = 6082 feet.)
					India-rubber.		Gutta-percha.					
	Diameter of single Wires in inches.	No. of Wires in Conductor.	Total weight in lbs. per knot.	Total diameter of Conductor=d.	Weight in lbs. per knot.	Diameter in inches=D.	Weight in lbs. per knot.	Diameter in inches=D.				
Red Sea Cable, tested by F. Jenkin before being laid	0·038	7	180	0·105	—	—	212	0·34	3·4	1·224	98·8	3,080,000
Malta-Alexandria, standard tested by Siemens	0·054	7	400	0·162	—	—	400	0·457	2·95	1·082	332·0	11,700,000
Wire covered by Messrs. Silver, intended for a channel line	0·024	7	86·5	0·071	115	0·232	—	—	3·48	1·233	212·0	6,572,000
Specimen, covered by Messrs. Siemens with india-rubber and gutta-percha, tested by Messrs. Siemens	—	1	42·5	0·059	12	0·100	16·2	0·136	2·3	0·833	106·0	4,863,000
Second specimen	—	1	42·5	0·059	12	0·100	35·0	0·168	2·85	1·047	460·0	16,780,000

The question of the relative merit of the two materials in this respect, though much vexed, is absolutely without importance. They both insulate well enough for every practical purpose. This will readily be allowed when the following fact is known. The current received through 2,000 miles of the Malta-Alexandria cable, maintained at 60 deg. Fah., would be only 0·7 per cent. less than that received through a cable perfectly insulated, or, in other words, covered with a material of infinite resistance.† If the cable, instead of being kept at 60 deg., were in warm latitudes, and maintained at 75 deg. Fah., the difference between the actual cable and perfection would be 2¼ per cent., instead of 0·7 per cent. Any further improvement in insulation can only serve to reduce this trifling per centage.

The insulation, when so good as this, has little or no effect on the speed with which successive signals can be transmitted through a cable. This speed depends on a second electrical property—viz., the specific inductive capacity of the insulator; or, in other words, on the relative magnitude of the statical charge which would be induced from the same source in Leyden jars of equal dimensions, with the dielectric made of the several different insulating materials.

In this respect, india-rubber is certainly better than any gutta-percha which has yet been produced. The annexed table E gives the results of some experiments made specially for this report by the writer. The last column contains the specific inductive capacity of each material compared with air taken as unit; the lowest number corresponds with the best material and the number of words which could be transmitted per minute through wires of equal dimensions, insulated with these several materials is simply inversely proportional to the numbers there given. Some experiments on old cables lead to the belief that the specific inductive capacity of the material then used was greater than that of the present gutta-percha. The correctness of the absolute values as compared with air depends on the accuracy of some of Professor Weber's experiments, but the relative values are unaffected by these experiments, and can be relied on. Messrs. Silver's wire was the best of those tested. Messrs. Siemens' wire was covered in the first instance with a small quantity of india-rubber, and then with a thicker coating of gutta-percha.

TABLE E.

NAME AND LENGTH OF CABLE TESTED.	Copper Conductor.				Insulator or Dielectric.				Approximate ratio $\frac{D}{d}$ *	$\log_{\epsilon} \frac{D}{d}$	Electro-statical capacity C of one foot in electro-static absolute units.‡	$I = 2C \log_{\epsilon} \frac{D}{d}$ Specific inductive capacity.
					India-rubber.		Gutta-percha.					
	Diameter of single Wires in inches.	No. of Wires in Conductor.	Total weight in lbs. per knot.	Total diameter of Conductor=d.	Weight in lbs. per knot.	Diameter in inches.	Weight in lbs. per knot.	Diameter in inches.				
Specimen of wire covered by Silver, 9½ knots long, intended for a channel line	0·024	7	86·5	0·071	115·0	0·232	—	—	3·43	1·233	1·144	2·82
Specimen of Messrs. Siemens' wire, 1,657 yards long	0·0295	4	43·0	0·059	13·0	0·114	52·25	0·177	3·00	1·100	1·38	3·036
Second specimen of Messrs. Siemens', 329 yards long	0·037	3	51·0	0·057	26·4	0·13	102·4	0·266	3·72	1·314	1·187	3·12
Specimen of gutta-percha tested at Messrs. Siemens', 1,758 yards long	—	1	82·0	0·066	—	—	80	0·206	3·121	1·138	1·837	4·18

Rattier & Co., Paris, H. M. (France, 1,428), exhibit some creditable specimens of gutta-percha covered wire, protected with lead, and with iron wire in the usual manner, for land and submarine purposes respectively.

(To be continued.)

* Where the conductor is a strand, d has been diminished 5 per cent. before taking the ratio $\frac{D}{d}$.

† Resistance of copper conductor per knot = 3·65 mercury units. Resistance of gutta-percha sheath per knot = 332,000,000 mercury units.

‡ These numbers are equal to the radius of a sphere of equal capacity to that of one foot of the cable: that is to say, a conducting sphere of this radius insulated in the interior, and very far from the inside, of a large hollow conductor, would hold the same charge as one foot of the cable when the difference of potentials between the sphere and surrounding conductor is equal to that between the internal wire of the cable and the surrounding water.

ON THE GAS BATTERY OF MR. GROVE, AND ITS THEORY.*

HAVING had during the past summer occasion to review minutely the theory of the voltaic pile, I was, by the nature of my work, led to go somewhat fully into an examination of recorded facts and observations in regard to the whole subject; and this by various writers, chemical and electrical, old and modern. The results of my inquiry and attendant experiments have compelled me to lay down different interpretations of the origin of the power and nature of the phenomena of the pile, from those usually adopted by the advocates of the chemical and contact theories, or of the theory of Davy, which makes both contact-electrical and chemical action essential to the origin and continuance of the current. Nevertheless, I may in passing observe that, with an important qualification as to the origin of the electric agency, I incline to a revival of the latter theory. My reasons for doing so will be apparent a little later. I know, however, that with respect to the theory of the voltaic pile, speaking generally, I dare not at present express fully my scientific convictions, since the facts on which I rely are in part second-hand, and, although the work of eminent men of former days, may be thought by some to need revision on account of our extended knowledge. At the same time it is right to say that I have no doubt as to the consequences of such revision. But with regard to the gas battery considered by itself, I have no such cause for hesitation; there everything of a chemical and electrical nature essential to the inquiry is apparently so open and under control and ready observation, that I do not see that I need, as to my facts and views on this subject, shrink from an appeal to the judgments of the competent readers of this eminently philosophical publication.

The gas battery of Mr. Grove, as most readers are aware, consists of a series of cells, each containing two tubes of glass sealed at one end, and in which are inserted by fusion long narrow platinum plates and attaching wires, the plates reaching a little below the bottom of the tubes. These tubes are partly immersed by means of a ground collar into a square three-necked Woulfe's bottle, the centre hole between the tube-holes being stoppered. The tubes are usually two-thirds filled—the one with hydrogen two volumes, the other with oxygen one volume—the bottle and remaining part of the tube holding the usual dilute sulphuric acid to complete the circuit. The platinum is, in order to promote contact with the respective gases and the liquid, covered with platinum-black; metallic contact between the tubes or to the galvanometer is made by mercury cups attached to the platinum wires. I have been thus particular in describing the form of cell, because my case rests upon the results obtained by a pair which I have constructed and charged in a similar manner in all apparent essentials, with only one important difference (as the fact turns out), namely, omission of the platinum-black. In my pair I simply use plain clean platinum, first burnished with agate and then further cleansed with tripoli, ammonia, and spirits of wine; so that it is chemically and electrically clean, as experiment easily shows. Thus far premised, and all being arranged, I proceed to experiment with each instrument. With Mr. Grove's pair, which I will call A, I get of course a powerful deflection with an ordinary good galvanometer; with the plain platinum pair B, none. The A-tubes left in metallic contact for some time show a tolerably rapid disappearance of the gases. The B-tubes left in contact for the same time, no sensible disappearance. But, more than this, the A-tubes left without voltaic metallic contact show a rather rapid rise of fluid, especially in the hydrogen one. The B-tubes in a parallel experiment, in which the time is not too long, show no alteration of level, but after several days a little hydrogen has disappeared: this I attribute to the difficulty of burnishing the edges of the foil used.

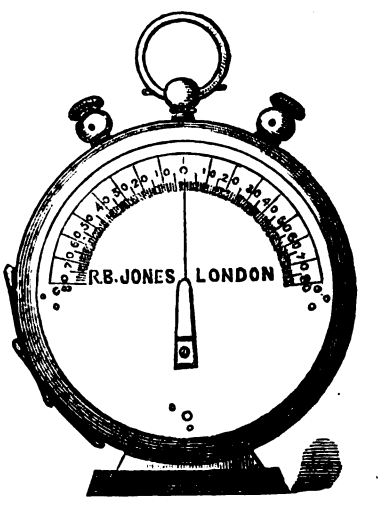
The whole of the facts needed for our purpose are now before us. There is, as might have been foreseen, evident chemical union of free gaseous particles, obtained by diffusion, in the tube containing platinum-black, and none sensibly in the plain platinum tube; and since in the one case there is a current following metallic contact, and in the other none, it follows, I humbly submit, that antecedent static electric action, produced here, I admit, by chemical action (but of direct combination, and not of indirect with simultaneous decomposition), is necessary to produce true voltaic phenomena. Contact in the wire, or disruptive discharge in the air, or convection in an external decomposition cell, restores the disturbed equilibrium of the chain. The fluid below, being part of the chain, suffers decomposition as a consequence of the discharge above, and, as Davy would allow, the now liberated gases react directly upon the free gases in the tube; and so a constant supply of active material is furnished for the production of fresh electricity, and hence the appearance of a current and of circulation. The antecedent chemical action and statical spark are no longer necessary, unless contact be broken, when all reverts to the original state, and the diffused and dissolved gases are again in requisition. Fresh contact, by allowing discharge of static electricity, will again renew the voltaic or galvanic phenomena.

Such I believe to be a true and philosophical account of the facts and consequences concerned in this remarkable instrument; and I venture to think it is one that will apply also to the water and salt-and-water excited battery, if not to the acid battery itself. Thus the rival theories find their place and application, but not in the order or manner supposed by their first and illustrious enunciators, Volta, Wollaston and Davy. If truth is found in these facts and views, chemists and electricians will readily see that such topics as passive iron, rusting of metals, and decay, and even general chemical action itself, may yet receive further elucidation from viewing them in the manner here attempted in the case of the gas battery. I may at once mention that the anomaly of free hydrogen being found with the nitrogen in some of Mr. Grove's eudiometric experiments become perfectly intelligible and regular by the considerations here evolved.

I am indebted to Mr. Gassiot, whose known kindness needs no comment, for the use of the Grove gas pair, and also to Dr. Wrigley for permission to carry on my experiments in his laboratory, aided by his instruments.

* By T. A. Malone, late Director of the Laboratory, London Institution.

JONES'S PORTABLE GALVANOMETER.



THIS is a very elegant, compact, and useful instrument for testing telegraphic wires, or for experimental purposes. From its small size, it can be conveniently carried in the waistcoat pocket, not being larger than a moderate-sized watch, which it resembles in appearance. Its diameter is about 1¾ inch, and its thickness ½ inch. It is furnished with a small ebonite stand, terminals, and a loop, to which a chain or guard may be attached. The coils are formed to suit the case, and are so arranged also as to have a greater electrical influence on the needle or magnet than the ordinary coils. The coils consist of considerable lengths of fine copper wire (No. 35). The needle is so placed within the coil that it can be magnetised when required without the necessity of removing it from its position. The instrument, from the smallness of its size and the perfectness of its arrangement, will, we have no doubt, be appreciated by engineers and practical electricians who superintend the construction and working of telegraph lines. It has been designed and constructed by Mr. R. B. Jones, electric telegraph instrument manufacturer, of 14, Nelson-terrace, City-road, E.C.

MEDITERRANEAN EXTENSION TELEGRAPH COMPANY (LIMITED)

The ordinary half-yearly general meeting of the shareholders of this company was held at the London Tavern, on Friday, the 5th inst., for the reception of the report of the directors, and the transaction of the general business of the company; Henry Moor, Esq., chairman of the board, presided on the occasion.

The Secretary having read the notice calling the meeting, and the report having been agreed to be taken as read,

The Chairman remarked that he had very little to say to them on that occasion; the company was in a prosperous condition, their cables were all right, and their traffic considerably increasing. Comparing the receipts of the current half-year with the last, they were very much better, being as £7,000 against £5,400; their weekly receipts being about £269 on the average. During the half-year there had been a break in the cable, between Alexandria and Malta which, however, had been made good, and had it not been for this, it was most likely that their receipts would have been double the previous, but he was sorry to say that another interruption had occurred on the same line; the lessees, however, had sent out a vessel to repair it, and, as the damage had occurred in shallow water, it was believed that it would very speedily be in working order again. Their receipts during the past half-year amounted to £437 more than the previous half-year, and it was a gratifying fact to be able to show that their staff was able to perform the work they had to do, however much that might be increased, whilst their expenses had increased only about £29, a sum hardly worth mentioning. A disadvantage the directors had had to contend with, was the fact that they could not get a proper settlement with the Italian government; they had only received payment for the quarter ending March, 1863, and there were now three quarters due from them, which they had a great difficulty in obtaining, and as they had to declare a dividend, they would have to borrow money of their bankers, for the purpose of paying it. The directors had done all they could to bring the Italian government to a settlement, and, not having succeeded, they had now applied to the Lords of Her Majesty's Treasury on the subject. The payment of a dividend of 4 per cent., free of income tax, and the sum agreed to be carried to the reserve fund, would absorb nearly the whole of their receipts for the past half-year, therefore the only way open to them for the payment of their dividends, was the plan proposed. He would now move "that the report and statement of accounts now presented, be received and adopted."

Sir James Carmichael seconded the resolution.

A Shareholder wished to know the meaning of the last item in statement of expenditure, "deduct Alexandrian lessees' proportion of rent for Malta offices, £23 19s. 9d."

The Chairman, in reply, said that last year there was an agreement between the company, and Messrs. Glass & Elliot, that they should share half the expenses of working the line, but, that agreement having expired, they thought that they would prefer keeping their own staff, which they have accordingly done.

The same Shareholder wished to know why interest should not be charged to the Italian government for the amount due, as they would have to pay interest to their bankers, if they borrowed money to pay their dividends, besides putting them in an unenviable position before the public?

The Chairman said that they could not claim interest on the account. It must be borne in mind also, that although they did not receive interest from the Italian government for the money they owed the company, neither did the company pay interest to those to whom they were indebted, otherwise they would have to pay on about £13,000 owing by them to other companies. If, however, the directors could get the opportunity of enforcing the payment of interest on the amount, they would not fail to do so. (Hear).

No other remarks having been made in relation to the report, the motion for its adoption was put, and carried unanimously.

The Chairman then moved "to declare the usual dividend at the rate of 8 per cent. per annum, on the preference shares, subject to the deductions for income tax," which, having been seconded, was carried unanimously.

The Chairman next moved "that a dividend of 4s. per share, equal to 4 per cent. per annum, free of income tax, be declared on the original shares," which, having been seconded, was also carried.

The Chairman then remarked that he had then come to an important resolution, which they could please themselves as to whether they would carry or not. In order to pay the dividend which they had just declared, it would be necessary that the directors should borrow the money to pay it with, and the amount they would require would be about £3,000. He had therefore, to propose "that the directors be empowered to borrow of their bankers, a sum sufficient to pay the dividends now declared," which, having been seconded,

A Shareholder said, that he should like to be informed when they were likely to receive their account from the Italian government, as he would much rather stop a little while for his dividend than that the money should be borrowed to pay it with; he had a great objection to borrowing money, especially for such purposes, and if they were likely to obtain a settlement shortly he would rather that the payment of the dividend be deferred.

The Chairman said that it was quite out of his power to say when the settlement would be made, he could only say that the directors would do all in their power to obtain it; it might be in a few days, or it might be much longer; the loan would not be taken for a fixed period, but merely as a current loan.

Mr. McDougal said that it might prove very disastrous to some of their shareholders not to receive their dividends at the usual time; some of them might be in poor circumstances, and were depending upon this money, and he thought it would not be well to disappoint them; the money had been earned, and was still owing, and would be sure to come, therefore it would make but little difference to them, and he considered that there could be no objection to borrowing it.

The motion, having been put to the meeting, was carried in the affirmative.

The Chairman then moved "that an amount of £700 3s. 4d., being 10 per cent. on the revenue, be carried to the reserve fund." At present they only had £547 16s. 7d. invested on the reserved fund account, arising from the fact of not having received their money from the Italian government; when the whole of their money was received from the Italian government, it would amount to about £1,700.

The business of the meeting having been declared by the chairman as having been brought to a close,

Mr. McDougal said that the meeting had yet a duty to perform towards their chairman and directors, he should therefore move that "the thanks of the shareholders be presented to the chairman and directors, for the manner in which they had conducted the business of the company during the past half-year."

Mr. Wisby, having seconded the proposition, it was put and carried unanimously.

The Chairman, in acknowledging the compliment on behalf of the directors and himself, remarked that they were glad to have met them under such favourable circumstances, and hoped that their next meeting would be much more so.

The meeting then separated.

ELECTRIC AND INTERNATIONAL TELEGRAPH COMPANY (LIMITED.)

The twenty-sixth half-yearly ordinary general meeting of this company was held at the offices of the company, Telegraph-street, Moorgate-street, E.C., on Thursday last, and was very numerously attended. The Hon. Robert Grimston, chairman of the company, presided on the occasion.

The Secretary having read the advertisement calling the meeting, the Chairman said that it was his duty now to lay on the table the register of the proprietors of the company, and affix the seal of the company thereto.

The report as printed and circulated having been taken as read, the Chairman said, that, eighteen years ago, Messrs. Cook and Ricardo, with a few other individuals, undertook to teach the world a new art, with what success the world now knew. They had to make experiments in all matters, and in what that company had done they had been servilely imitated. Compared with what that company had done for telegraphy, others had done but very little; and he felt that the public owed them a debt of gratitude for what they had accomplished. When the company was first started, the price charged for the conveyance of messages was a very high one; but as telegraphic communication became more known and appreciated, the company reduced their scale of charges to the public. In 1850, the maximum charge was 10s. for a message, it then was reduced to 8s. 6d., afterwards to 5s., and so on; and this course has been adopted ever since by the directors as necessity called for it. The tariff is found to require occasional revisions, and this has the special attention of the directors, and in all cases they cannot get through without a loss; but the profits made on some portions of the line make up for the losses on others. When they came to analyse the receipts, they find that one-fifth of the income arises from the Irish traffic. In undertaking this portion of the business, they entered upon it with doubting and hesitation; but having begun it they found that they must go on with it, even to the South of Ireland: they were doing their work there right well, and the business increases steadily. One-third of their income was derived from Continental traffic. The plan adopted by the Government of what is termed the Austro-Germanic Union, has caused a reduction of the tariff all over the Continent; but the tariff of this company remains as it was before, whilst its business has increased, and it can only be limited by their capability of carrying messages. As to their general and home system, they have stations all over the country; other telegraph companies have not the means which this one has at their disposal, and no opposition can materially affect them. The expenditure for the last half-year has been large; but if a large amount of work is done, the expenditure will crop out in the shape of wages, stationery, gas, &c. But in order rightly to judge of the matter, they must compare the expenses with the amount of work done, they will then see that the expenditure has been kept at the lowest point, the receipts now showing more than 100 per cent. in their favour. Another item called for remark, and that was the cost of maintenance; this their engineer had gone into. Now if any one was about taking a long walking tour, he would not start

with shoes partly worn out, but would see that they were in perfect order, or he would soon be compelled to come to a stand; just so it was with telegraph lines,—unless they were repaired effectually and maintained efficiently they would soon break down, and loss would result. The shareholders had a right to know that they had their money's worth for what they had expended during past years; and he thought that their Electrician's report furnished them with that information. During the violent gales which occurred in November their system was tested very severely, but their working was never interrupted; and after each storm the report of their superintendent on the state of their lines was most satisfactory. If their income is to amount to £137,150 during a half-year, it can only be done by an efficient and costly system. With their balance of £50,000 they should not only be able to pay their dividends, but have sufficient to resuscitate their reserve fund, which was a matter of great importance, for business was subject to very many vicissitudes, and it was desirable to be prepared for them. There might be a great continental war, and their business might be considerably interrupted, and thus their receipts might fall short; but if they had this fund to fall back upon, however protracted the war might be, they would not feel its effects to such an extent. He felt that they must be thankful for such a prosperous half year, which had enabled them to place their property in so good a position. He must call their attention to the capital account. A portion of that building was on freehold, and another portion on leasehold ground, the lease having seventy years to run. Your directors are desirous of making the property their own, and for this purpose they write off £800 per annum, in order to accomplish this, and in twenty years they will stand rent free. Until the last half year they adopted a similar course in regard to their central offices in Founder's-court, which they had now disposed of. In the earlier days of the company it was, perhaps, necessary to have large and attractive premises, in order to draw the attention of the public; but the directors considered that as the company was now so well known they might do with less expensive premises, and consequently they had removed here, where they had their galleries constructed, and were able to carry on their business equally well, whilst they have been relieved of a ground rent of between £300 and £400 a year, and the £5,839 which was due to the company at their former meeting for the sale of their premises the directors have now placed on deposit, and propose, with the sanction of the shareholders, to add to the reserve fund. It has been the lot of the directors mostly to report the death or removal of some one of their number, and they have to do the same now, in announcing the death of one of their oldest and most valued members, Mr. Thos. Critchley, and the resignation of the Right Hon. Sir John Lawrence, on account of his appointment as Governor-General of India; and as the board now consists of fifteen members, we do not propose to fill up the vacancies, and have passed a resolution to that effect, as they were empowered by the Company's Act. He had further to inform them of a change in the principal officer of the company. Mr. Fourdrinier, who had filled the office of secretary to the company for the last fifteen years, and had served them faithfully and zealously, had now retired from that office, and he should have to ask them to grant him a retiring pension of £300 per annum. He would now move the adoption of the report.

MARK HUISH, Esq., seconded the motion.

Mr. REID wished to know whether 5 per cent. was paid on the £75,000 debenture stock. (The Chairman—4½ per cent. is.) He could not understand how it was that the accounts were presented so long after the quarter had closed, and that so many weeks were allowed to pass by before the half-yearly meeting was held. If the accounts of a great country like this could be made up in a few days, he could not see why the accounts of this company could not be furnished sooner.

The CHAIRMAN said that nothing would be easier than to have their meeting two or three days earlier, and to get their accounts out sooner—it was a mere question of expense; but they must employ extra clerks, and it would entail an outlay of several hundred pounds, which they considered to be unnecessary. Their other meetings had fallen about this date for several years, they had got into that groove, and he thought that no inconvenience arose from it. With respect to the debenture debt, it was a portion of new capital, and it would be a very unusual course to pay off capital out of revenue. These debentures were borrowed for a term, and they had not the option of paying them. They were getting more than 5 per cent. for their money.

A SHAREHOLDER wished to draw attention to the paragraph in the electrician's report as to the insulation of the wires. This insulation had been a very serious thing from beginning to end. When Mr. Clark was going to upset the whole insulation some time ago, it cost the company some thousands of pounds, and now it was proposed to have a new system of insulation. He should like to know what was intended to be done, as it would cost them a large sum of money.

The CHAIRMAN was sorry that the electrician was not present to answer for himself, being unfortunately laid on a bed of sickness; but he believed that he was fully justified in putting that paragraph in his report, concerning the insulation, for the average time in which a message was sent to Cork from London was two minutes. The insulator used was brown earthenware, composed of three parts, and put together with an ebonite pin: it cost about half the price of any other, and was the best, costing about 6d.

A SHAREHOLDER wished to ask a question about their submarine cables. At a former meeting the Chairman had announced with much *éclat*, that the directors had dispensed with the steamship, *The Monarch*, but he found that they were in for it again, for £2,354. He wished to know whether *The Monarch* had really been dispensed with or not.

The CHAIRMAN: No, it was not; for ships would drag their anchors, and it was necessary to have a vessel at hand to repair the cables.

Mr. LANG wished to know when the contracts with the railway companies expired. The stores in hand were put down at £50,375. Was it necessary to keep so much on hand, or might not some of it safely be disposed of? The amount of £72,613 due, seemed to be a very large one; was it not possible to reduce it? And what was the policy the Board intended to adopt in competing with the Magnetic and other companies?

The CHAIRMAN said, he was asked whether it was necessary to keep £50,000 of stores on hand? It was absolutely necessary to have a very large amount on hand; it has been very much reduced from this time last year; they could not carry out the working of the company without it, and if they were valued, they would be found to be worth considerably more than they were set down at. The £72,000, due on the 31st December last, was amounts due from the various Government offices, railway companies, the press, and other sources, and, after the 31st December, these amounts kept tumbling in, and were most probably, by this time, all in the hands of their bankers. As to the United Kingdom and the Magnetic Companies, their plan was to charge the same rates as those companies, and, if possible, to beat them out of the field, by doing the work better than them.

Mr. EVANS considered that the directors had the confidence of the shareholders, and that it was not for the benefit of the company that every question should be answered; it might, however, perhaps not be objected to his asking whether the auditors' attention had been called to this item of the stores, as to their actual value, for, in regard to railway stores, an amount was often put down in the accounts, of a most serious description, and taken for granted, without any enquiry or trouble being taken to ascertain their real value.

Mr. ROLLS (auditor) stated that he had made every enquiry as to the value of the stores, and was sure that they were honestly worth the amount charged against them.

The motion that the report be received and adopted, was then put from the chair, and carried.

The CHAIRMAN said that he had to propose that a dividend of £3 10s. per cent., for the half-year, be paid out of the net profits of the company, which, having been seconded by M. Huish, Esq., was carried unanimously.

The CHAIRMAN then proposed that a retiring pension of £300 per year be granted to Mr. Fourdrinier, their late secretary, in consideration of the long and faithful services rendered by him to the company during the last fifteen years, which having been seconded,

Mr. REID said that he was sorry their chairman should be the first to propose to make their company a pension society. What had Mr. Fourdrinier done to call for such a sum being granted to him for life? He would tell them something about him in connection with Nutt & Gamble's patent, which was for an instrument to send telegraphic messages, and connected with it was Colonel Wylde, Fourdrinier, and Gamble the younger. The Electric Telegraph Company opposed it, and after a good deal of money spent in law, and hearing before the Lord Chancellor, a compromise is entered into; Colonel Wylde is made director of the company, Mr. Gamble is made private secretary to the chairman of this company, Fourdrinier is to be provided for, and poor Nott, the inventor, is left to starve. Through the active agency of Mr. Gamble, he gets Fourdrinier appointed secretary to this company by displacing a man who held the appointment, and who was vastly his superior in everything relative to telegraphy and mental qualifications. This was Fourdrinier's entrance into this company; some of the shareholders—if not all—will say, not a very respectable entrance. However, he is possessed of two qualities that deserve to be noticed. The first is his excessive severity to all poor instrument clerks, by enforcing fines of the most aggravating character for the merest trifles. The second quality is his excessive toadyism to the directors; and if a new dictionary is constructed, the word "fawningism" will be properly personified in the character of the ex-secretary. It was understood that Mr. Gamble put him into the place to keep it warm for himself, but, alas! Mr. Gamble, in some unfortunate moment, said that the directors were no better than a set of old women, and for that irreverent expression got discharged, and Fourdrinier still kept his position. He has now for a long term of years been receiving from this company the fabulous sum of £750 per annum; and now, when his term has at last finished, our good-natured chairman has not the moral courage to say, "Mr. Fourdrinier, this company does not require your services any longer; we require a more active, intelligent, and efficient man to fill the office of secretary." In place of taking this honest and straightforward course he, along with some other of the directors, have recommended that he be placed on the pension list, taxing the future resources of this company to the tune of £300 a-year, equal to £1 per day for every working day of his natural life, which may be twenty years—equal to a tax of £6,000 or £7,000. He would only add that, if out of this £750 per annum he could not provide for himself and family—if he has any—he ought to have done so; according to an ancient writer, "He that provideth not for his own household, has denied the faith, and is worse than an infidel." He would now, with their permission, read an extract from the *Times* of this month as a contrast to the excessive liberality of our directors towards the ex-secretary.

The case is a painful one, but will show the way in which our business is conducted. Mr. Reid then quoted from the report of a trial of one of the late *employés* of the company receiving 16s. per week—a starvation point of wages, less than a labourer who carries the hod—and requested the meeting to look at the two pictures, Mr. Fourdrinier and this young man. Mr. Reid then proceeded to say that any stockbroker's clerk would have done all Mr. Fourdrinier's work for £100 a-year, and have done it a deal better.

Mr. Long would ask a question as to the legality of giving this pension. He would warn the directors against getting the company into a mess. Not that it would be worth his while to challenge their proceedings, but any one might file a bill in Chancery against the directors on the point. Other companies certainly had done the same kind of thing, but he did not see the wisdom of doing it in that company, or the authority for doing it. The directors had power to pay for any services rendered, but they had not the power to give away money for services not rendered. It was a precedent which was illegal, and without express authority they could not do it. Granting of pensions is not within the ordinary business of the directors, and well deserves the attention of the board, and it was not fair to be done without some explanatory remarks. Many other shareholders like himself would like to know the nature of the extraordinary services which have been rendered, for if £750 per annum was the value of the services given, why should £300 per annum be given now that those services were not rendered?

Mr. Fraser had great reluctance in doing anything which might appear hostile to the board of directors, but he thought that the meeting were called upon to acknowledge a vicious principle, for every man with such a salary as £750 ought to make provision for himself and family; and the same principle, if applied in this case, may be applied to every other servant in the company's service. He believed that Mr. Fourdrinier had no particular merit in his mode of discharging the duties of secretary more than any ordinary secretary, and it would be too bad to tax the shareholders for this. He would support any other proposition rather than a tax for services not rendered.

A Sharehlder thought that Mr. Fourdrinier had not done anything to entitle him to £300 per annum. He thought it a very awkward proposition, and if that continental war came upon them, of which the Chairman had spoken, that £300 per annum might be found a very serious matter. He must, therefore, oppose it, for every other clerk of the Company might expect the same thing if this were agreed to.

Mr. Reid then proposed an amendment to the effect, that taking into consideration the large sum Mr. Fourdrinier has been receiving for several years from this Company, it is the opinion of this meeting that he has no further claim upon its funds, which, having been seconded, the Chairman remarked that he felt disappointed at the way in which the proposition had been received, as he expected the Proprietors would have been unanimous on the subject. Mr. Fourdrinier's connection with the Company ceased merely from a re-arrangement of the offices, and not from ill health, and a saving would be effected by the alteration. Under the circumstances, he thought that very few of the Proprietors would have felt any difficulty in granting the pension. He thought that perhaps the most convenient way would be to take a vote for the current year, and then have a special meeting to consider the subject.

Mr. Bidder hoped that the Shareholders would not be led away by Mr. Reid, who was guided by a little personal feeling. (Mr. Reid: I have no personal feeling in the matter.) He would suggest that they pass this vote for the current year, and take the Shareholders' opinion as to the future. He believed that the Shareholders would conform to the policy of the Directors.

Mr. Evans remarked, that from the explanations given by the Chairman, the matter came before the meeting in a different shape; it appeared that from the re-arrangement of offices, Mr. Fourdrinier's services were not required, and he thought that the Shareholders would not be wanting in consideration of that matter.

Other amendments having been proposed, Mr. Frazer said, that has they had funds in hand, had they not better vote that a sum of money be given to Mr. Fourdrinier at once, they should then have done with it, and there would be an end of the matter.

The Chairman, in answer to a question, said that they had done away with their metropolitan surveyor, and had engaged Mr. Weaver, at a salary of 1,000*l*. per annum.

Mr. Long wished to know whether the re-arrangement of the officers had saved more than 300*l*. a-year, to which the Chairman replied that the amount payable would be about the same.

Mr. Frazer said that he objected to the principle of this pension, for if they agreed to it they did not know what might come upon them; he would therefore move, "That in lieu of the proposed pension of 300*l*. per annum to Mr. Fourdrinier, the sum of 1,000*l*. be voted to him."

Mr. Evans seconded the proposition, which having been put to the meeting, was carried.

The Chairman then moved the re-election of the following retiring Directors:—Lord Alfred Paget, M.P.; W. H. Smith, Esq., jun.; Lieutenant-General Wylde, C.B.; and Mark Huish, Esq., which was carried unanimously.

The Chairman then proposed the re-election of James Rolls, Esq., as Auditor, which having been agreed to, the Chairman announced the termination of the business of the meeting.

A vote of thanks to the Chairman and Directors, for the manner in which they had conducted the business of the Company during the past half-year, having been cordially agreed to, the meeting separated.

CORRESPONDENCE.

THE PNEUMATIC APPARATUS.

To the Editor of the Telegraphic Journal.

Sir,—The letters signed by Mr. France and Mr. Harwood, contain no positive evidence whatever, but are a loose bundle of deductions and inferences, that hardly merit a reply. Mr. Harwood says he supposed this invention to be Mr. France's, because "shortly after Mr. Andrews ceased to be engineer to the Submarine Telegraph Company I was appointed superintendent of the Cromer station, whence the longest cables leave the English coast, and it fell to my lot to have to remove from some of the most important lines, and replace with the pneumatic relay, instruments which Mr. Andrews had invented, or which, at least, I know *him to have had constructed subsequent to the invention of the pneumatic instrument.*" Your readers will be surprised to learn that one of these pneumatic relays was actually fitted up, and at work, months before Mr. Harwood was appointed at Cromer; preceding his predecessor, Mr. Fernhaber, and during the superintendentship there of a very efficient servant of the Submarine company, Mr. Shaw, who was still in charge at Cromer when I resigned the Submarine service.

On the 9th of September last, Mr. Courtenay, the late esteemed Secretary to the Submarine Company, who well knew this to be my invention, at my request telegraphed to Cromer, as I wanted a spare model for the Persian Gulf, "Have you any of Andrews' pneumatic relays at work on the cables, and have you any spare ones?" The reply was, and the message now lies before me:—"25 service; 2.32 p.m.; 9th Sept., 1863. Cromer to Courtenay, London; Yes. One on each line, but no spare one.—Harwood." I make no comment, except that this discussion at the above date had not arisen, and that Mr. Harwood's views have changed somewhat, between the 9th of September, 1863, and the 30th of January, 1864.

Now this apparatus, and the modifications made by Reid, of those already proved on the line, were coming forward about the same time. No. 3, as Mr. France calls it, was a very perfect instrument. Mr. France himself telegraphed me of this:—"Your apparatus works perfectly; nothing could go better." I dare say I shall find this message. Mr. Shaw, the then Superintendent at Cromer, reported the same of it, and I have now a letter from him to that effect lying before me. There was no necessity, therefore, to press forward the pumps. I think that I am correct in asserting that no other apparatus were ordered by me subsequently to the pump being proved on the line where No. 3, as a distinct instrument, separate from any Morse arrangement, had been a considerable time working. I take it, if an engineer wanted engines to work his railway, and certain descriptions had been proved effective, he would not refrain from ordering more engines required for the service, with modifications, because he had an invention, of which he thought highly, coming forward.

Mr. France appears to have but a very poor opinion of an inventor who invents No. 1, No. 2, and No. 3, and, according to this gentleman's ideas, every invention should be a sort of miraculous conception; instantaneously conceived, as instantaneously applied, and as instantaneously discovered to work perfectly, and to remain a perfect instrument for evermore. *Eureka.*

How many inventors will be of opinion that, had Mr. France possessed any experience whatever in inventions, his views might, possibly, have been more modest.

As to the question of the date of the accounts, Mr. France should be aware that those who make the preliminary apparatus charge on the finally completed apparatus as delivered; dates, in these cases, are no guide to the commencement or germ of an invention.

Respecting Mr. France's statement that, if he is not mistaken, Mr. Banks used to use his name in speaking of the pump relay, Mr. France appears to forget that trials at the office, and experiments on the Belgian wires, with his instrument were made by me for a considerable period. I always spoke, during these experiments, of this apparatus as mine, and certainly Mr. Banks, during this time, always spoke of it and treated it as mine. Mr. Banks, however, must answer for himself.

The fact is, Mr. France has neither disproved my facts, supported by positive evidence, nor has he brought forward any facts on his own side. If Mr. France, therefore, desires me to pay any further attention to his letters, they must not consist too exclusively of that description of reasoning immortalised by Mr. Cuttle.—I am, Sir, your obedient servant,

Melbourne Cottage, North Brixton, Feb. 11, 1864. W. Andrews.

To the Editor of the Telegraphic Journal.

Sir,—In reply to Mr. France's letter about Mr. Andrews' pneumatic relay, I must beg to observe that, even if I were as ignorant of mechanics as Mr. France is pleased to say, still that does not prove him to be the inventor of the arrangement, and the date of the bills would not prove when the work was put in hand, because all first experimental work—sometimes

extending over long periods—is always put in the gross charge of the complete instrument when delivered; and as to my handing Mr. France over to the workmen, it was simply for convenience, and that only about the pump keys, for, as it so happens—*unfortunately* for Mr. France—the *first relays, with Mr. Andrews' arrangement, were not made at the factory at all*, but by a workman employed by us off the premises, who did the work at his own house. All the instructions, with the drawings and alterations made from time to time by Mr. Andrews, were done in my presence, and given to me by him, and such instructions I gave direct to the man, whom I can confidently assert *Mr. France never saw upon the subject.* The workmen he saw at Aldersgate-street were only employed making the keys, and those alone, as I above state; so that Mr. France has cut up his own case in endeavouring to show "that, as Mr. Banks knew all about it," it is not likely he (Mr. France) namely would have been employed to see the workmen direct. He never did see them about the relays; not that I consider this important, as Mr. Banks was continually seeing the workmen during the progress of the work, and yet he does not claim to be the inventor.

After Mr. Andrews had resigned from the Submarine Company, and Mr. France had more instruments made, they were all made on the same model; but Mr. France never claimed them as his.

I am, Sir, your obedient servant,
G. W. GUY.

Windsor-terrace, City-road, Feb. 10, 1864.

[*Erratum.*—In Mr. Guy's letter, which appeared in No. 4, page 44, instead of "making pneumatic arrangement; *also* for the key," read "making pneumatic arrangements for the key."]

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—I never used Mr. France's name in connection with the pneumatic arrangement, as Mr. France states I did.

I am, Sir, your obedient servant, J. BANKS.

St. John's Wood, Feb. 12, 1864.

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—I was surprised upon looking over your first number to find the pneumatic arrangement for multiplying the effects of return current accredited to the invention of Mr. Andrews, as the system had been attributed to Mr. France from the day of its introduction, and was generally referred to in connection with his name. When the "Pump Relay" first made its appearance, it was certainly most carefully nursed by Mr. France, and I am confident Mr. Banks has upon more than one occasion given him credit for the idea. Will you kindly insert this in your next number?

I am, Sir, your obedient servant,
J. BOURDEAUX,
Dover, Feb. 9, 1864. Superintendent of the Dover Station.

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—In reference to the question of the invention of the pneumatic apparatus, I beg that you will allow me to confirm Mr. France's statement, that Mr. Banks, in order to distinguish this instrument from any other of the kind, habitually gave it the name of its inventor, and alluded to it as "France's pump relay." There can be no possible misunderstanding as to the truth of this, and I can further state, that in the course of the many conversations between Mr. Banks and myself, on this subject, I never heard him ascribe its invention to any other person. I can also testify that Mr. France was in this Company's service when this instrument was introduced, and took the earnest interest in its performance natural to its inventor. Having read the directly opposite statements contained in Mr. Banks' letter, I am of course quite prepared to see my assertions denied. The matter can then only became a question of our relative credibility, and in that stage I shall be content to leave it.

I am, Sir, your obedient servant,
Submarine Telegraph Company, JAMES STEPHENSON,
58, Threadneedle St., E.C., Feb. 9, 1864. Assistant Superintendent.

[We think that this discussion should terminate here. Our readers will, no doubt, agree with us that its prolongation would only create unnecessary ill-feeling.—ED. T. J.]

CARTHAGENA AND ORAN SUBMARINE CABLE.

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—As the information contained in our letter of the 5th inst. may convey some false impression in the minds of your readers, we beg herewith to hand the following, since received from Mr. C. W. Siemens.

"The cable parted at a splice made at our manufactory during the shipment, and the hemp at this particular place on investigation was found discoloured and damaged by some chemical agency, as acid, which by some unhappy accident must have had access to the place while making the joint. In all other parts of the cable the hemp is as good and unchanged condition as ever."

We are, &c.,
Per SIEMENS, HALSKE, & Co.,
3, Great George St., Westminster, S.W., Lloeffer.
10th February, 1864.

TELEGRAPHIC NEWS.

THE ORAN AND CARTHAGENA CABLE.—By the Bombay mail, which arrived at Southampton on the 11th inst., intelligence has been received that the French steamers *Eclaireur* and *Dix Decembre*, from Oran, arrived at Carthagena on the 29th, having succeeded in laying down, for the second time, a submarine cable which is to connect both parts. [We hope the information will prove correct.—ED. T. J.]

THE TELEGRAPH CLERKS' PROVIDENT FUND.—We are glad to hear that the London General Omnibus Company have contributed £2 2s. to the Telegraph Clerks' Provident Fund.

THE TRANSMISSION OF THE QUEEN'S SPEECH.—We were in error when we stated that the Submarine Telegraph Company employed six wires on the occasion—the number was five. We are assured that along two of the wires messages were transmitted at the rate of 25 words per minute; and when we consider that the wires were either buried in earth or submerged in water, which subjected the current to the retarding influence of induction, the transmission was exceedingly rapid. The message was also transmitted to Cologne along two wires at the then rate of 11 words per minute.

TRAIN SIGNALLING.—It had been arranged that, on the 10th instant, their H.R. the Prince and Princess of Wales, the infant Prince, and their suite were to travel along the South-Eastern Railway. We understand that among the precautions adopted to ensure safety the Electric Telgeraph stood prominent. Under the superintendence of C. V. Walker, F.R.S., and his staff, who were accompanying the Royal train, a complete set of instruments were provided for communicating along the train, and by means of which, in case of accident, information could be sent to any station on the line. A handsomely bound message book was also provided for their Royal Highnesses' use during their stay at Hastings.

OVERLAND TELEGRAPH.—Below we give a highly interesting and important letter from the President of the California State Telegraph Company to J. J. Southgate, Esq., containing proposals from the company for the establishment of telegraphic communication between Victoria and San Francisco. The distance from Fort Vancouver, to which point the company expect to have the line completed in a few weeks, to Olympia, with which port there is regular weekly steam communication, is just 120 miles, making a total of less than 250 miles which would then have to be constructed to complete the connexion. The portion between Olympia and Victoria might very easily be laid as a submarine line, at probably less cost than by the rugged an unsettled land route, and the whole sum required from Victoria to finish the line between that place and Portland or Fort Vancouver would be trifling compared even with the amount of interest proposed to be paid to the projectors of the route between the Canadas and that colony. The commercial advantages to Victoria of the Californian route would be quite as great as those offered by the other. The only difference is in case of a war with the United States, in which case, of course, the line would be useless:—"Californian State Telegraph Company, San Francisco, November 17, 1863. Dear Sir,—This company proposes next year to extend its lines of telegraph to Victoria, if any encouragement shall be afforded that will justify it in doing so. The incomplete line from Yreka in California, through the State of Oregon, to Fort Vancouver, in Washington territory, which has been for two or three years in process of construction, has just passed under the control of this company, and will be completed within a few weeks. Thence to Victoria a line would be very expensive, and could not be remunerative for many years to come. If, therefore, this company undertakes to build the line, it will ask some assistance from the people of Vancouver's Island and British Columbia, by way of cash subscriptions, to be refunded in telegraphing or in the full paid stock of this company, which pays regular and certain dividends. But the principal aid or encouragement to be sought for at that end of the line will be a grant from the Government of such privileges as will secure the line for a reasonable number of years against competition in the business between Victoria and San Francisco—contingent, of course, upon the line being completed within a certain period, to be clearly specified. No subsidies will be asked for from the Government, nor any franchises that can in any way interfere with the proposed line across the continent through British territory. I need not say anything to you of the very great importance to the people of your province of a speedy telegraphic connexion with the balance of the world. I presume that you are fully alive to its importance, and it appears to me that the result will be accomplished a year or two the sooner by a little well-directed assistance to the enterprise now proposed. This company owns all the telegraphic lines and franchises in the states and territories west of the Rocky Mountains, and I presume there can be no doubt as to its ability or intentions. I shall be greatly obliged to you if you will have the kindness to make inquiries in the proper quarters and communicate with me as to the prospects.—Very respectfully yours, H. W. CARPENTER, Pres. Cal. State Tel. Co.—J. J. Southgate, Esq."

THE OTRANTE AND AVELONA SUBMARINE CABLE.—In another part of the Journal a notice will be found of the safe arrival of the ship *Semaphore*, with the above cable on board, at Malta. We have been informed that the vessel has now reached its destination, and that the shore ends have been laid, and intelligence of the submersion of the whole cable is hourly expected.

The Electric and International Dramatic and Discussion Club.—The first meeting of the Discussion Class, in connexion with the above club, took place, as per announcement, February 10th; Mr. F. Perry presiding. After a few introductory remarks from the chairman, Mr. Young proceeded to deliver his essay upon "Women, morally, socially, and intellectually considered." In the discussion which ensued, Mr. Brandon fully agreed with Mr. Young that the present unsuitable employments for the female sex were at variance with their interests, and tended greatly to impair their future usefulness in life as wives and mothers. Mr. Garrard then continued that, though he fully endorsed the sentiments of the last speaker, he thought that women ought to have more congenial occupations open to them, and strongly deprecated the employment of men in drapers' shops. The discussion was considerably enlivened by the jocose and humourous remarks of Mr. Plainway, and the proceedings terminated with a cordial vote of thanks to the secretary for his very able essay.

Denmark, Sweden, and Norway.—The Submarine Telegraph Company give notice that during the interruption of communication by the *direct route* to the countries in consequence of the war in Schleswig-Holstein they have increased their charges.

The Persian Gulf Cable.—Letters have been received from Sir Charles Bright and staff, dated Bombay, the 13th January, stating that the *Kirkham*, with the mid-ocean portion of the cable on board, had arrived safe at that port, and that the expedition for laying down the cable was to start the next day, commencing with the section from Gwadel. All reported well, and the weather favourable.

The Pacific Telegraph.—Telegraphic facilities are rapidly increasing along the Pacific slope. A line is now being constructed from San Francisco to Portland, Oregon. Workmen are at work in extending the wires from Sacramento, along the line of the Pacific railroad, across the Sierra Nevada, making it, when completed, the third line belonging to this company crossing these mountains. Men are also at work in the Carson Valley, extending the line westward from this end to meet it.

The Cape.—The *Argus*, of the 19th of December, states that the electric telegraph is now in operation as far as Mossel Bay from Cape Town, and would be completed to Graham Town by the end of the year. The Cape of Good Hope Telegraph Company was to complete the line from Cape Town to Graham Town very shortly after the departure of the last mail for Europe, and it was to be available for the use of the public on the 15th of January. Cape Town was already in communication with George Town, and Graham Town with Uitenhage. The only link which is wanted to complete the communication throughout being in the Langeklof. The distance between the termini is over 600 miles, along which the whole of the poles have been fixed. All that which was required now was a short length of wire. The company had not published its scale of charges, but it was known that the same had been subjected to and approved of by the Government. The cost of transmitting a message of twenty words from Cape Town to Graham Town was to be 12s. 6d., and from Cape Town to Fort Elizabeth 10s. For the same number of words the charges from Cape Town would be as follows:—To Caledon, 2s. 6d.; Swellendam, 3s.; Riversdale, 4s.; Mossel Bay, 5s.; George, 5s. 6d.; and Uitenhage, 8s. Messages would also be forwarded by post, and special messengers to King William Town, according to arrangement, and hence by telegraph to East London. The charges between intermediate stations would be on the same scale as those already mentioned. Although the charges may appear as rather high, the question of the distance and the comparatively small number of messages which would be transmitted would not admit of any material reduction.

The Correspondent of the *Times* furnishes the following information from Malta on the 6th instant:—The *Cossack*, 20, screw frigate, Capt. W. R. Rolland, left at noon on Monday for Bengazi, with Mr. Saunders, electrician to Messrs. Glass, Elliot, & Co., to test the Malta and Alexandria cable, after landing her passenger on Wednesday sailed on return to Malta, arriving here on Saturday morning. M. de Sauty, electrician to the same firm, has passed through Malta to Alexandria to test the Alexandria end. He is expected back to-night, to await the arrival here of the cable ship, which is on her way from England, when he will proceed in her, with an efficient staff of engineers and workmen, to repair the fault. From the testing already made at Bengazi it has been pretty surely ascertained that no electrical defect exists, and that the interruption is owing to some mechanical accident, which is believed to have happened nearer to Bengazi that at first supposed. It was most probably caused by a ship's anchor. Wind and weather permitting, no difficulty is anticipated in a speedy and complete repair being effected. While on the subject of telegraphs I must mention that the electric cable which arrived here last week in the English screw steamer *Semaphore* is for the Italian Government, to replace that laid by Messrs. Newall & Co., between Otranto and Avlona, on the Albanian coast, and which has defied all attempts to repair it. The new cable was made at the works of Mr. Henley, the manufacturer of the Persian Gulf cable. This short line will prove of great service in completing the communication with Greece and different parts of the Levant. There is a rumour that the Italian Government intends shortly to lay a cable between Marsala and Tunis, to be constructed also by Mr. Henley, which will place Malta in almost direct telegraphic communication with that regency and the province of Algeria. The Mediterraenan Extension Telegraph Company have announced that the line between the Dardanelles and Scio is interrupted, and that messages must consequently be sent by post to Gallipoli.

THE HALF-YEARLY REPORTS OF TELEGRAPH COMPANIES.

THE Reports which have appeared in our columns of the operations for the last half-year of several Telegraph Companies are upon the whole of the most encouraging character, and will have been read with satisfaction by the commercial and scientific friends of one of the greatest achievements of modern times.

The Electric and International Telegraph Company's report shows a steady improvement in the Company's revenue, the last half-year's receipts exceeding that of the preceding half-year by £20,076, the total receipts being £137,150. It appears that the extension of the Company's line to the south of Ireland has been a very profitable one, owing to the great number of American messages received; and we may reasonably infer from the fact that when the Atlantic Cable is laid, the above line will be one of the most important and, no doubt, remunerative in the kingdom. The Company also are reaping the advantages which necessarily must accrue from the extension of the telegraphic system throughout Europe.

The total expenditure for working charges and interest on debentures for the half-year amounted to £86,582, leaving a surplus of net profit on the six months of £50,568, which enabled the Company to declare a dividend at the rate of 7 per cent. per annum, leaving after such payment the large sum of £16,447 to be placed to the credit of the trust fund for the purpose of replacing and repairing submarine cables. It is admitted that this balance is larger than that carried forward on previous occasions, and that the Company's submarine lines are now all in excellent working order. The electrician, Mr. Cromwell F. Varley, also reports all the land circuits in excellent working order, and that during the late severe storms the system remained unimpaired. Several valuable improvements had been introduced in the mode of insulation, which had considerably expedited the rate of transmission, and a system of establishing direct communication between the most important stations had been adopted, which would avoid, to a considerable extent, clerical errors and delays, and save much manual transmission. The following table shows the half-year's increase in the extent of the Companies' lines:—

	Dec. 1863.	June, 1863.	Increase.
Miles of line	8,230	8,006	224
Miles of wire	39,042	36,391	2,121
No. of instruments	4,489	4,163	326

The Mediterranean Extension Telegraph Company has, after a series of vicissitudes, been enabled to report to its proprietary that their prospects were rapidly improving; the balance-sheet for the past half-year showing the Company to be in a better position than it has been since its commencement; and had it not been for the unfortunate interruption in the working of the Malta and Alexandria Cable, it was believed that the receipts would have been nearly doubled as compared with the previous year. It is a source of great satisfaction to understand that the Company's cables continued in excellent working order, and that the accident which since the publication of the report has occurred to one of the Company's cables, will be speedily repaired. The Directors were enabled to recommend a dividend of 8 per cent. per annum on the preference shares, and 4 per cent. per annum on the original shares, also adding 10 per cent. on the gross earnings to the reserved fund. The prosperous condition of this Company, its increasing traffic, and the satisfactory state of its important lines, must greatly tend to the development of ocean telegraphy as a remunerative commercial undertaking.

The Directors of the Telegraph to India Company intimate to the shareholders that the remaining assets had been disposed of, and that there were no further liabilities. The Company is in receipt of £2,500 per annum from their Alexandria, Cairo, and Suez line, leased to Messrs. Glass, Elliot and Co. at the above yearly rental. In the case of this Company, as in that of the Mediterranean Extension Telegraph Company, the interruption on the Malta and Alexandria cable has not been without its effect. In glancing over the receipts, we find that the 200 miles of cable intended for replacing the defective portions of that of the Red Sea Company, and which cost some £20,000, has been disposed of for £8,000—rather a small sum, taking into consideration the price of gutta percha at the date of its manufacture and its present market value. We have, however, been assured that the cable is in an excellent state of preservation.

The British and Irish Magnetic Telegraph Company report favourably of its operations during the past year, showing a continued increase of revenue. The expenditure, owing to increased business and cost of maintaining the lines, had been larger, great improvements having been effected during the year in several of the principal districts. The Company's submarine lines between England and Ireland were partially interrupted, and it was determined to have the cables thoroughly and efficiently repaired, which has now been effected, involving an expenditure of £5,000. The Directors, however, despite the heavy outlay, have recommended a dividend at the rate of 4½ per cent. per annum for the first half, and 5 per cent. for the second half-year, thus making 4¾ per cent. for the year against 4½ per cent. for 1862. The extension of the Company's lines—and more especially that between Cork and Cape Clear, with the view of intercepting the steamers from America—has fully justified the expenditure. The total income for the year is put down as £108,267 18s. 7d., and the working expenditure as £69,649 14s. 8d.

The London District Telegraph Company still continues to progress steadily. It appears that, notwithstanding the heavy expenditure incurred in the course of the past half-year in consequence of the severe gales towards its close, the receipts for the same period show an increase of £109 17s. 1d., and £327 0s. 10d. over those of the corresponding period of 1862. The Company have now upwards of fifty contracts for the maintenance of private lines, and have entered into arrangement with the Metropolitan Railway Company for the exclusive commercial and general telegraph business on that line. The system of telegraphs for the use of the Fire Brigade has also been completed, and works satisfactorily.

During the half-year new offices have been opened in Ratcliff and London Wall, and the cost of all these works has been added to the capital account, and are all represented as remunerative. Total amount received for messages, rent of private wires, &c., £4,326 4s.

Thus, having rapidly glanced over the reports hitherto published, we have no reason to complain of the present, or to doubt the future of Electro-Telegraphy.

SUBMARINE TELEGRAPHY.

We have on more than one occasion directed the attention of our readers to the importance of submarine telegraphy as the only means of uniting England with America—"a consummation devoutly to be wished." Since the failure of the Atlantic cable in 1858, the public have looked askance at all submarine projects, and "knowing ones" have shrugged their shoulders as if dubious of the practicability of ocean telegraphy. The improvements which have been effected in the manufacture of deep-sea cables, the ingenious and efficient machinery of late employed in paying them out from vessels into the ocean, coupled with the successful submergence in Europe of no fewer than fifty-two lines of telegraph, encourages the hope that future attempts to unite the old with the new world will be attended with success. We append a table, showing the number of lines laid to the present date, and, with one or two exceptions, they are in efficient working order:—

Submarine Telegraph Cables which are now in Successful Working Order.

No.	Date when laid.	From	To	Number of Conductors.	Length of Cable in Statute Miles.	Length of Insulated Wire in Statute Miles.	Depth of Water in Fathoms.

* The cable between Algiers and France has been injured (supposed to be by lightning).
† Injured by a ship's anchor, but now being repaired.

Thus it will be seen that there is in Europe an aggregate of 5,625 statute miles of submarine telegraph actually in operation, laid in lengths of from 4½ to 1,535 miles, in depths ranging from 15 to 1,580 fathoms. Since 1854, 95 lines, in lengths of from 120 feet to 23 miles, have been laid in the American rivers, and are found to work well, particulars of which we append:—

Submarine Telegraph Cables in Operation in the United States, Canada, and the Lower British Provinces.

The fact of so many cables having been successfully laid, demonstrates the practicability of submarine telegraphy, and we hope that this method of communication will prove more felicitous in the future than it has been in the past. An attempt is being made by the Atlantic Telegraph Company to raise a new capital, in order to carry out the scheme which proved so disastrous to all concerned in 1858. We wish them every success, and trust that next year they will be enabled to submerge a cable in the bed of the Atlantic, and, by facilitating correspondence with the new world, realise a handsome return for the capital invested in the undertaking.

REPORT OF THE BRITISH AND IRISH MAGNETIC TELEGRAPH COMPANY (LIMITED).

The directors beg leave to submit to the proprietors the accounts for the past year, which show a continued increase in the revenue of the company. The expenditure is larger, partly the natural result of an increased business, but mainly owing to the additional cost of maintaining the lines, great improvements having been effected during the year in several of the principal districts.

In the course of the past summer first one, and shortly after, the other of the Irish cables, both of which had previously been in good working order, gave way, and it became necessary to repair them without delay. The directors foresaw from the first that the cost would be very considerable, and the unavoidable expense was increased by the unusually stormy and unfavourable weather in August and September.

The communication with Ireland, although much curtailed, was never interrupted, and the repairs of both cables were effected in a satisfactory manner, leaving reason to hope that no further outlay will be required for some time. Bearing in mind, however, the age of the cables, and the uncertainty attending all such means of communication, the directors have determined to charge the whole of this expense, amounting to nearly £5,000, to the past year. The amount available for dividend has thus been reduced much below the actual amount of the net earnings of the year; but the directors have, nevertheless, been able to declare dividends at the rate of 4½ per cent. per annum for the first half, and 5 per cent. for the second half year, thus making 4¾ per cent. for the year, against 4½ per cent. for 1862. After doing so, they are still able to make a small addition to the reserve fund. They think that this statement will prove satisfactory to the proprietors, and that the course adopted of meeting a heavy extraordinary expense out of the year's revenue will commend itself to their approval.

Several additions have been made to the company's lines in the past year; the principal has been from Cork to Cape Clear, with the view of intercepting the steamers from America at the earliest possible moment. The service is one of difficulty and great uncertainty from various causes, but the directors do not regret the extension.

Considerable further progress has been made in the substitution of overground wires for the remaining underground sections of the lines, and the anticipated improvement in the working has thereby been realized.

J. C. EWART, Chairman.
E. B. BRIGHT, Secretary.

Liverpool, February 12th, 1864.

REPORT OF THE LONDON DISTRICT TELEGRAPH COMPANY (LIMITED).

The net receipts for the half-year ending 31st December, 1863, show an increase of £109 17s. 1d. over the previous half-year, and £327 0s. 10d. over those for the corresponding period in 1862.

The directors are glad to inform the shareholders that an agreement has been entered into with the Metropolitan Railway Company, granting to this company the exclusive commercial and general telegraph business on that line, and offices will shortly be opened at all of their stations.

During the half-year offices have been opened in Ratcliff and London-wall, and some additional agreements entered into for private telegraphs. The London Fire Brigade Telegraph has also been completed, and is reported upon satisfactorily. The cost of all these works has been added to the capital account, and they are all remunerative.

The directors regret that the charges for maintenance and repairs are unusually heavy; partly to be accounted for by the expenses consequent on the severe gales towards the close of the half-year; partly by the greater portion of the instruments and batteries at most of the stations having been repaired or renewed; and partly by a new cable having been required under a portion of the London Docks.

The directors have been enabled to provide for these expenses, both on the capital and maintenance accounts, and have not, therefore, thought it advisable to make further issue of either the original or forfeited shares at present, or to exercise the borrowing powers conferred by the articles of association. When additional capital is required it may be obtained from any of these sources.

It should be borne in mind that the second half of the year is always the less remunerative, owing to the vacation months intervening, and generally the most expensive in point of maintenance of lines, &c.

Pursuant to the articles of association, two directors, C. K. Dyer, Esq., and S. Gurney, Esq., M.P., retire from the board, but being eligible offer themselves for re-election.

The auditors likewise retire. Mr. Sandell offers himself for re-election, but, since the notice of meeting, Mr. M. Chubb has resigned. It will, therefore, be the duty of the shareholders to elect his successor.

The directors have further to state that, in consequence of Mr. Chubb's sudden resignation, the present accounts are signed by only one auditor.

THE INTERNATIONAL EXHIBITION, 1862.

(Continued from page 78.)

6. *Insulators for Land and Aerial Lines.*

No change of importance has occurred in the construction of land lines since 1851. Iron wire of about No. 8, B.W.G. (⅙ inch diameter) is still generally adopted for the conductor in England; larger gauges, such as No. 4, or even No. 1, are adopted for direct transmission over long circuits). In France, wire of 4 millimètres diameter (=0·16 inch nearly) is used.

Earthenware, stoneware, and glass insulators are now considered inferior to those made of poreclain. Stoneware is generally porous; glass is found to break easily, and to condense surface moisture to a great extent. Porcelain insulators are imported in large numbers from the Continent, and some apparently good specimens are shown by J. B. Cappellemans, Sen. H. M., Brussels (Belgium, 860), and by H. Schomburg, Berlin (Prussia, 2177).

S. W. Silver & Co., M. (United Kingdom, 2960), exhibit insulators made entirely of hardened india-rubber or ebonite, a material which has been used to a considerable extent in coating the iron pins of porcelain and other insulators. From tests made by Messrs. Silver, it would appear that the hygrometric qualities of ebonite are extremely good, and no serious deterioration of the

material has been observed during an experience of about two years.

Mr. Meyer (Hamburg, 130) also exhibits good ebonite insulators.

C. F. Varley, M. (United Kingdom, 2981), exhibits insulators intended for use where very good insulation is required, as in lines of 200 miles and upwards. They consist of an upright iron bolt or pin, the head of which is covered with ebonite, or vulcanite, as it is sometimes called, on which rests a porcelain inverted cup. This cup is again covered by a second cup of porcelain, on the top of which the wire to be insulated rests. By this arrangement, one, or even two, of the three insulating covers may be cracked or porous, or otherwise defective, without sensibly injuring the insulation of the line. Mr. Varley's insulators are also made with a special quality of stoneware made by compression from a peculiar clay. This stoneware is at least equal to porcelain.

Mr. Varley showed the Jury a record of experiments in which the deflection indicating a loss during heavy rain from lines insulated in this manner was not more than 5 divisions, when the deflection from a wire of equal length, fixed on similar insulators, without vulcanite on the pins, was 90 divisions, and from a wire supported by single inverts, 370 divisions. During a fog the relative losses were 23, 55, and 405 respectively; these numbers were examples taken at hazard from a great number of experiments.

Mr. Varley considers that the insulation resistence of a line in the worst weather, expressed in Mr. Varley's units, should not fall below the quotient of 40,000 by the length in miles. Mr. Varley's unit is equal to 26·6 of Siemens' units.

The British and Irish Magnetic Telegraph Company, M. (United Kingdom, 2864), exhibit two forms of insulator designed by Sir Charles Bright.

1. A porcelain invert with vertical sides and a small spread of surface, cemented over a straight iron bolt and nut; soft india-rubber is placed round the bolt inside the cement, to prevent the expansion of rust from cracking the porcelain cup. This plan of using india-rubber is said not to be of much use, but the insulator affords good insulation at a low price.

2. A double bell, with a shackle bolt, intended for use where great strain comes on the wire. The double bell is held in a wrought-iron fork, by a bolt passing through the axis of the two bells, and two eyes of the fork. The other end of this fork forms a hinged shackle. The wire is attached between the two bells; it ends at each post, and is connected across to the next section by a short wire outside the insulators. This form is specially suitable to terminal poles and over-house work, where great spans are combined with sharp curves or angles; the hinge of the shackle allows each insulator fork to take the line of the wire attached to it. These insulators are extensively employed for over-house work in London, Dublin, Glasgow, &c.

Siemens, Halske, & Co., M. (United Kingdom, 2959), exhibit two forms of insulator, which they call respectively the strainer and intermediate insulator. They use the strainer to secure the wire at about every 500 yards with six or eight "intermediate insulators," supporting the wire by hooks, in which it can slip when a change of weather expands or contracts the wire.

The strainer is composed of the following parts:—An inverted porcelain cup is firmly cemented in a cast-iron bell, provided with a vertical flange bracket. By means of this flange the insulator is fastened to the post with wood screws. A wrought-iron stalk is cemented inside the porcelain cup; this stalk is enlarged at the end, where two notches or recesses are formed of such shape as to allow the wire to be secured by wedges or cottars. The wire between the notches is bent into a circular loop to allow the wire to be slackened in cold weather, or when repairs require it.

The intermediate insulator is of similar construction, but the stalk ends in a hook, in which the line wire rests free to move to and fro. The cast-iron bell protects the porcelain cup from injury, and also from wet, improving the insulation. These insulators are strong but heavy, and are not so cheap as some of the forms usually adopted. The intermediate insulators are quoted at 1s. 3d. complete, and the straining insulator at 3s. 3d. They are extremely well adapted for use in countries where repairs are difficult, and supervision imperfect, owing to their strength and good fastenings.

Reid Brothers (United Kingdom, 2949) exhibit several insulators. 1. A large glass invert with stout glass stem, used in South America. The glass stem is simply dropped into a hole bored in a wooden cross-bar. 2. A double bell insulator, supported by an iron bracket from beneath, with a vertical iron bolt through the centre of the two bells; the glass or porcelain part of this insulator is similar to that exhibited by the British and Irish Magnetic Company, and already described. It can be removed and replaced without withdrawing any bolts or nails from the wooden post. 3. A cap insulator used between Birmingham and London. This insulator, made entirely of stoneware, without any iron fastening, is slipped over the top of the post, which it protects against wet. It is a cheap form. 4. An insulator intended for lines to be erected in haste without poles. The upright pin of a common invert is bolted to the butt end of a strong horizontal wrought-iron spike. This spike can be driven into trees, walls, houses, &c., and the insulators fixed with great rapidity. A large number of them have been supplied to the army.

The Danish State Telegraph (Denmark, 123) exhibits some good and strong insulators used in Denmark.

7. *Posts for Aerial Lines.*

The old wooden post is still generally used to support the insulators and wires, but a large number of wrought-iron posts have been used with advantage in India and other countries, where wood is subject to rapid decay. The District Telegraph Company also supports its wires used in over-house work by cylindrical telescopic wrought-iron poles, stepped on to the ridge tiles of house-roofs and stayed with iron wire ropes.

Siemens, Halske, & Co., M. (United Kingdom, 2959), exhibit wrought-iron telegraph posts, which they expect will last so much longer than wooden posts, as possibly in many countries to be the cheaper form in the end, although entailing greater expenditure at first. Each post consists of three square wrought-iron rods (three quarters of an inch square for intermediate, and one inch square for terminal posts), firmly secured at their upper end by a wrought-iron ring and wedges to a wooden top similar to the top of a common post, and at their lower ends fixed to three cast-iron plates buried in the earth. They are further strengthened by two or more wrought-iron stays fixed between the rods at different heights, and wedged to them by means of wrought-iron collars. The insulators are fastened to the wooden top. The various parts of these posts are easily transported, and need only be put together on the spot where they are intended to be erected. They offer a small surface to the wind, and stand firmly on a strong base. They are well adapted for countries where the means of repair are not at all times near at hand, and the communication slow and scarce. The smaller post weighs 2 cwt.

W. T. Henley, H. M. (United Kingdom, 2908), also exhibits wrought-iron posts designed with the same view. They are formed of four thin plates of iron, each so bent that its cross section forms a quadrant with radial external flanges at each end. Four of these plates bolted together from the post, and the flanges running from top to bottom, stiffen the structure. Mr. Henley uses either a wooden or a wrought-iron top and a large flat cast-iron base.

8. *Novel Construction of Aerial Lines in Large Towns.*

The Universal Private Telegraph Company [Professor Wheatstone, Juror] (United Kingdom, 2978), has been formed with the view of providing independent or private wires for the use of large firms, and others having establishments in different parts of the same town. A large number of conductors are required to carry out this idea, and the method by which they have been provided is cheap, novel, and entirely successful; the system was devised by Professor Wheatstone, and may be described as follows:—

Straining posts are fixed on the tops of public buildings or private houses at distances of about a mile, and their positions are so arranged that when joined by straight lines a series of nearly equilateral triangles is mapped out. From each of these straining posts, in six different directions nearly equidistant from each other, pairs of steel or galvanized iron wires or ropes are stretched to the six adjacent strainers distant about one mile. Intermediate supporting posts without insulators are fixed at convenient distances. A rope consisting of a bundle of about fifty copper wires, each separately covered with india-rubber (exhibited by Messrs. Silver), is suspended from each pair of iron wires by loops at short intervals along their entire length. The ropes terminate at the straining posts, and the free ends of all the wires are brought into a box. By means of suitable connections in this box the wires arriving from one direction can be joined to those proceeding in any other, and thus the wires may be combined in every desirable manner, and the combinations changed as required. From these boxes the single wires also proceed, which complete the commu

nication between the main lines and the establishments to be placed in connection with them.

The triangulations above described are of course only extended to those parts of a town where a large number of conductors are required, and may be intermitted where other means of carrying the rope are more convenient or economical.

9. *Land Lines Underground.*

Underground wires are now used as little as possible, owing to the decay of both gutta-percha and india-rubber under these circumstances.

C. V. Walker, H. M. (United Kingdom, 2983), shows a very simple form of trough in which underground wires, where unavoidable, are protected against the effects of the atmosphere or against mechanical injury.

A V groove is cut from a rectangular piece of wood by two saw cuts; the piece cut out is turned over so as to form a cover, which is lashed down by wires at short intervals. The insulated wires lie in the covered trough bedded in sand and tar. The adjacent lengths of wood are spliced together by a V of thin hoop iron, driven half into one and half into the other.

INSTRUMENTS EMPLOYED IN THE TRANSMISSION OF MESSAGES.

1. *Codes used or proposed, in which the Letters of the Alphabet are represented by new Arbitrary Symbols.*

The transmission of messages is still in a great measure effected by arbitrary signals, depending for their signification on the order in which various series or groups of currents succeed each other. Each letter of the usual alphabet is represented by a distinct group of currents, or of the signs which they are made mechanically to show or record, and much ingenuity has been exercised in devising codes which should use the fewest currents in the representation of words as written at full length in the usual alphabet.

The elements from which alone codes of this nature can be formed are the following:—

1. The presence of a positive current.
2. The presence of a negative current.
3. The change from one current to the other.
4. The absence of both currents.

5 and 6. The duration of the positive and negative currents respectively.

7. The duration of the absence of all current.
8. The strength of the current.

These elements clearly could not all be combined in any one code.

The Morse code is framed on the combination of a long and short current of the same kind, separated by intervals of three different lengths; the shortest used between each current, the next between each group representing a letter, and the longest between each series of letters representing a word. Reverse currents are now frequently used to produce these intervals on the recording instruments, but the code was framed without reference to their use. The long and short currents are generally called dashes and dots, from the marks which they produce on the paper band of the original Morse receiver.

A code, which may be called the Steinheil code, is framed on the combination of short, positive, and negative currents of equal length, with intervals of three different lengths, as in the Morse code. In other words, the alphabet when written is formed of groups of positive and negative dots.

Both of these codes can be read by the eye with moving needles, or by the ear with bells, as well as written on paper. The Steinheil is the shorter code of the two. In both care is taken that the letters most frequently used shall be expressed by the shortest groups of signals.

A Morse code common to all usual languages is now almost universally adopted, and the Steinheil alphabet can readily be made to correspond to it by letting, say, a positive current stand for a dot, and a negative for a dash.

Wherever, as in short land lines, currents can be made to succeed each other with indefinite rapidity, the number of currents used in a code is of less importance than the simplicity of the apparatus required for their transmission and reception; but where the number of currents that can be transmitted distinctly in a given time is limited, the number used for a word becomes a matter of commercial importance. Mr. Whitehouse and Professor W. Thomson both proposed codes for use on the Atlantic cable, which were more advantageous than the Morse or Steinheil codes.

T. Allan, M. (United Kingdom, 2850), exhibits a code which appears to the writer to be, as compared with the number of reversals required, the shortest yet published. In this code, as written, every letter is composed of a group of perfectly similar dots separated by three sets of intervals, as in the other codes: but Mr. Allan's apparatus is so arranged as to print a dot at each change of current, whether from positive to negative, or from negative to positive; while the maintenance of either current, or the complete interruption of all current, indifferently produces the intervals. Thus Mr. Allan uses what we have called the third and seventh elements; whereas the Morse code uses the fifth and seventh elements, and the Steinhill code the first, second, and seventh elements.

Mr. Whitehouse used the third, fifth, and sixth elements. In the usual Morse alphabet, if reverse currents are used, two reversals are necessary for each dot or dash; but in Mr. Whitehouse's alphabet, modified by Professor Thomson, each reversal produces a dot, which corresponds to the maintenance of either current. So far Mr. Whitehouse's and Mr. Allan's codes are on a par. Mr. Whitehouse, however, in order to denote any interval longer than the shortest used between the dots, was obliged to reverse his current, and maintain it for a longer time than that used for the dot; the longer intervals between words or letters were thus marked by lines. Mr. Allan, on the contrary, simply maintains his last current or interruption, and needs no fresh reversal to express the pause or interval, whatever its length, and gains in this respect an advantage over all other codes known to the writer. Mr. Allan's code is evidently the offspring of his automatic system presently to be described, but it might be used quite independently of that system.

The Morse, Steinheil, and similar codes are equally adapted for transmission directly by hand, or indirectly by mechanism, and by voltaic, induced, or magnetic-electric currents. The instruments used in connection with these codes, as distinguished from those used in step-by-step dial and printing telegraphs, will be first described, beginning with the instruments used by hand for direct transmission.

(*To be continued.*)

LONDON DISTRICT TELEGRAPH COMPANY (LIMITED).

THE tenth half-yearly ordinary general meeting of this company was held on Thursday last, at the offices of the company, 90, Cannon-street, London, Robert Taylor, Esq., Chairman of the Board of Directors, presiding; a large number of shareholders being present.

The SECRETARY having read the advertisement calling the meeting, the report was agreed to be taken as read.

The CHAIRMAN then said, that it would be seen from the statement of accounts presented to them, that the receipts of the company had not arrived at that state to which it was hoped at their last meeting they would have attained, but it was satisfactory to know that they were improving, as their balance sheet would show. When first he joined that company, he did so because he believed that it would be an useful and profitable company, and that it would be eagerly sought after. In New York the telegraphic companies paid something like 10 per cent., and he thought certainly that in London, the ready aid which its operations would afford to the inhabitants, would have been so appreciated that its financial affairs would have been placed in a more prosperous condition; but though that had not been the case at present, yet he hoped that the time would arrive when the company would right itself, and be as it ought to be. The Metropolitan Railway Company had entered into an arrangement with them, by which they had the entire right over their lines, and he believed that it would turn out to be very profitable. The Magnetic Company have in the past behaved in the most kind and liberal manner towards that company, and they have continued the same aid to the present time. He wished he could say the same of the Electric and International, for had they behaved in the same way as the Magnetic, their affairs would have presented a different appearance. He would now call their attention to a fact which, as shareholders, they should all be made acquainted with, namely, that their receipts throughout the month of January had increased £20 per week, and if they should succeed in going on at the same rate during the next half-year, when they again met, they might expect to see themselves so much improved in their finances as to be able to meet all their expenses, and after being able to do that, they would require very little more to enable them to pay a dividend. That was the state of affairs during the past half-year, and he had now only to move the adoption of the report, and the statement of accounts.

Mr. SHEWARD seconded the motion.

Mr. Hardy Wells said that he could not help thinking that the report now presented was of a very discouraging character, and gave very little hope for the future. Three half-years back their balance at the bankers was £947, the following half-year it was only £742, and this half-year it was but £438, which he considered to be very unsatisfactory. Under such circumstances, therefore, he thought it was necessary that the shareholders should ask the directors to put the domestic economy principle into practice, and cut down all expenses within their power. It would be seen that £3,000 had been paid to the directors alone for the management of the company. Now, that did appear to him to be too much for so small a company, and he would request the shareholders to ask the directors, in common language, only to pay themselves according to the means of the company. The company was but small, and he knew that the directors had its welfare as much at heart as the shareholders had; and he considered that the best thing they could do was to ask them to reduce their numbers. They had now seven directors, and if three of them would consent to take the place of the seven whilst the company was in its present low state, he thought that they would soon be much better off. He believed that very much of the success of the company was owing to their excellent secretary, Mr. Curtoys, and he thought that, with his able assistance, they might do for the present with three directors, and thus effect a saving. He should like, also, that they would have but one auditor, instead of two, and thus reduce their expenses, especially as it would be seen that one had audited the present accounts. They saw that all the directors were not necessary, for one of them (Sir C. Bright) was some thousands of miles away, and was likely to be so for some months to come.

Mr. Mitchell did not rise to grumble, but to express his gratification at the way in which the directors had managed the affairs of the company, and in bringing them so far within the prospect of having a dividend. He was, however, inclined to the idea that one auditor might be sufficient, as their object just now was economy, and that would produce a small reduction in the expenses. There were two items put down in the accounts—salaries, £456; wages, £2,167—why could not both these be charged under one head, as he considered salaries to be wages? There was a suggestion he would also wish to offer to the directors; it was, that he did not think that they made themselves sufficiently known to the public—they did not advertise as they ought to do. If they would erect a kind of box in some of the leading thoroughfares, as they did in Paris, and advertise their stations and terms, they would find it greatly increase their business, and it might be done at a very little expense; but he would leave that for the consideration of the board. He could not sit down without expressing his gratification at the prospects of the probable ultimate success of the company.

The Chairman, in reply to Mr. Mitchell, said that the Metropolitan Board of Works would not allow such erections in the public streets as those he had just mentioned. With regard to the items salaries and wages, they were put down in that manner so that the shareholders might ask any questions in relation to them which they might think fit; the salaries being for secretary, &c., and the wages the payments to the various clerks, &c. He might inform them that it was a source of continual pain to the directors that they found themselves unable to pay those young ladies in the manner they ought to be paid. Holding positions of responsibility, as those young persons did, the directors felt that it was not doing justice to them, and their wonder was how they were enabled to make both ends meet; as it was, he regretted to say that they were frequently losing them, from the fact of their going to other companies, where they received better pay.

Mr. Cable.—By the articles of association the accounts should be audited by two auditors. On the present occasion it appeared that they were only audited by one. He wished to know whether the directors were satisfied with that? By the report he found that Mr. Chubb had sent in his resignation as auditor. He was not quite satisfied with this statement. He should therefore like to know whether Mr. Chubb had sent in a resignation or not, as he had heard some rumours about him which were not very creditable?

The Chairman said that the directors were as much taken by surprise as Mr. Cable, for they had sent out their notices, according to the articles of association, when they received a notice from Mr. Chubb, from Paris, resigning his appointment. Mr. Sandell thereupon undertook to audit the accounts by himself, and, from his well-known position in London, the directors believe that his audit will be taken as satisfactory.

Mr. S. S. Taylor said that in the report there was an item of expenditure of £479 for works; but, seeing the difficulties of the company at the present time, he thought that they ought not to be laying out money from the capital account until they had received something for what they had already invested. Their money had now been lying for five years, and they had received no dividend. He considered that £20,000 out of their £50,000 had gone in waste. He really did think that, under the circumstances, every attention ought to be paid to economy. He was not at all disappointed with regard to the company, for he thought that when they got their revenue to £10,000 they should be doing well. They had got to nearly £9,000 now, and he thought that they ought to be able to make some profit out of that. They must, therefore, keep down the expenses, and then they would very shortly produce a dividend. He would suggest whether the charges for supervision could not be kept down? As to wages, they all knew how difficult it was to keep pace with them. He wished to ask a question with regard to the rental. They were going to receive a larger amount in the way of rental. This, however, did not appear much greater than last half-year. Stationery was put down at £236. That seemed a large amount: a great quantity of stationery ought to be obtained for that sum. He merely threw out these as hints. Then there was travelling expenses, £48. He did not quite understand that. All those items ran up, and it would be as well to look at them and see whether they could not be reduced. He also considered that 15 guineas was too much to be paid to each auditor. He thought that, under the present circumstances of the company, the directors should forego for a little time their remuneration, and so bring its affairs into a paying condition. If he were a director of a company like that, he should be very sorry to take anything out of it for his services.

The Chairman, in reply, said that Mr. Taylor had brought several things before them. He could assure them that the directors had nothing to keep back from the shareholders; they were anxious to furnish them with the fullest information on any subject connected with the company—no question would be considered too searching; for his own part he could never connect himself with any company where there was anything to be kept back from the shareholders. With regard to the wages, he could inform them that the directors took it in turn to go through them every week, and it only grieved them that they were compelled to pay their staff so badly. With respect to the rent, they had hoped to have been able to have brought that down lower; they had now let the house to a great advantage, and they had got the tenant of that portion of it to allow them the use of that room for their meeting, so saving them two or three guineas for the hire of a room at the London Tavern. As to the stationery account, that must, of necessity, be a large item in a company like that; they were served by contract, and from what he knew, by his connection with other companies, he must say that they were supplied at a much less rate than was usual. Travelling expenses, &c., £48, had been mentioned; this arose from repairs of lines, collection of accounts, &c., but he might inform them that there was not a sixpence put down in the accounts but what went under the searching eye of one of the directors, who attended to those matters especially. With regard to the expenditure on the capital account, the directors were very anxious to obtain the London Fire Brigade traffic under Captain Shaw, seeing that it would be an element of great profit to the company ultimately, and they succeeded in their attempt; for this, however, they had to construct lines, which have been charged to the capital account, but from which they expect to reap a remunerative profit, and if they had not done it, another company would. As to the remuneration of the directors, he could assure them that they did not hold their office merely from motives of profit; they did not desire to remain in office, and, if the shareholders thought that they could get any body of men to serve them better, they were quite willing to resign their positions. He would repeat, that it was only because he thought he saw in the company elements of usefulness that he connected himself with it; he was, however, bound to say that at present it had not realised his expectations, although he believed that it would ultimately. "'Tis not in mortals to command success, but we 'll do more, for we 'll deserve it." There might not be blue sky now, but they should see it by-and-bye.

The motion for the adoption of the report was then put, and carried unanimously.

The Chairman then proposed that C. K. Dyer, Esq., and S. Gurney, Esq., M.P., be re-elected as directors of the company, which having been seconded,

Mr. Cable said that he must congratulate the shareholders that Mr. Taylor had succeeded to the chairmanship of their company. Mr. Gurney was well known in the City of London, but he was hardly ever present at the meetings of the board, and, as the question arose whether the number of the directors should not be reduced, and by the articles of association he found they could be reduced to five, he would recommend that the present vacancies should not be filled up. Mr. Taylor spent a vast amount of valuable time for the interests of the company, and was always at his post, and deserved their best thanks.

Mr. Austin believed that Mr. Gurney would prefer not being re-elected. It would be no very great object for him to be a director, especially as his time was so taken up with other duties; but he (Mr. Austin) felt that the company gained a great deal of influence in other directions through his having a seat at the board. Now their success depended greatly on their relation with other companies, and he believed that they should not have survived if they had not kept on good terms with them. Mr. Dyer is a director of the Magnetic Company, and Mr. Gurney is a director of the Submarine, and by their influence the company was benefited, for they received a commission for all the messages which they delivered to or for them, and the Magnetic had assisted them very materially.

Mr. Wells had no personal feeling towards the directors; he only wished to put the matter before them, as to taking remuneration for their services until their revenue and expenses balanced. He believed that the company would yet become a great success; there were all the elements of success in it, and it only required time to develop it. He was well aware that the directors did not hold their office for the amount of money they received, and he believed that it would give greater confidence if it went forth to the world that they received no remuneration for their services.

Mr. Tromp knew, from inspection of the wires through London, that they were in an excellent state, and he believed that the directors had done everything in their power to keep them so.

A SHAREHOLDER wished to know whether there would be any alteration in the mode of transmission and delivery of messages in the future, for he had found much difficulty from the inaccuracy with which the message was taken and the slowness in delivery.

Mr. SHEWARD had taken a very great deal of interest in the company, and wished to see it work well, and, for the purpose of testing it, he had gone to different stations where he was not known and sent messages, in order that he might ascertain correctly how it worked, and he had found it to work well. He thought that it was a very unfair thing for the gentleman who had just spoken to come into that room and charge the directors with mismanagement, without having first spoken to the manager about what he had to complain of, in order that it might be looked into. They were in the habit of sending about 1,000 messages per day, and in not more than one per cent. of them was there a mistake. In testing the rapidity with which the messages were delivered, he found them to be delivered in a much shorter time than he expected. The first part of the morning and the afternoon were the busiest parts of the day, a much greater number of messages being sent then than in the middle of the day; and if these messages were to be sent more rapidly, they must keep a much larger staff of boys than they now did, or have a different kind of messenger, for they all knew what boys were when they went on an errand, if they only came across Punch and Judy. The cost of maintenance had greatly increased during the past half-year, but that had arisen from circumstances over which the directors had no control, the gales which had occurred having caused damage to their wires. The balance at the bankers was less than it formerly was, being a natural consequence of the expense they had been put to. The best friend to the management of the society was he who came to the office and pointed out the errors that occurred, so that they might be rectified.

A SHAREHOLDER must bear his testimony to the rapidity and general accuracy with which the messages were delivered, and the attention always paid to any instructions which might be given.

The CHAIRMAN considered that it was not right for such charges to be brought forward at the meeting as had just been made; they had a most excellent and obliging Manager and Secretary, of whom, on account of his being present, he could not say all that he might say, or ought to say, and if these complaints had only have been made to him as they ought to have been, he would not have rested until he had found out the cause, either of the error or delay. So far as he (the Chairman) was concerned, if he had not wished to have brought the ship safely into deep water, he should have given up long ago, and it was neither kind nor generous towards the directors to bring forward such charges on this occasion, especially when by calling at the office at the time, they would have been remedied. He could only say, that anything which the directors could do for the welfare of the company without starving it, would be done. He had always found it very false economy to starve the staff required to carry out the objects of a company. The observations made by Mr. Wells and others, would receive the most serious consideration of the directors when they next met.

The motion for the re-election of Messrs. Dyer and Gurney, as directors, was then put, and carried unanimously.

Some discussion then ensued as to the election of auditors.

The CHAIRMAN then proposed Mr. Sandell and Mr. Eames to be the auditors for the year ensuing. They all knew Mr. Sandell, from his having filled the office of auditor before; and as Mr. Eames had been in the habit of attending all their meetings, and catechising the directors, the shareholders could not, perhaps, select a better man to watch over their interests.

Mr. TROMP wished to know how much was paid to the auditors? (The CHAIRMAN: Fifteen guineas each.) He hoped the shareholders would ask the directors to pay them ten guineas each, instead of fifteen. If the company was in a better position they would have no objection to pay them.

Mr. EAMES was glad to find that they intended to have two auditors. He would rather have filled the office for nothing than that there should have been but one, for they had just now seen, in their own case, the importance of having two appointed. If he should be chosen as one of the auditors, they should have all the ability which he could bring to bear for the good of the company, as they well knew that he had always done his best for its prosperity.

Mr. WELLS suggested that Mr. Eames accept the office gratuitously.

Mr. AUSTIN thought it was not good policy to get work done for nothing, for where boards did their work for nothing it was generally found to be badly done, whilst it was their wish to have everything done as well as possible.

Mr. SANDELL wished to say a word about remuneration. He gave a deal of time in his earlier days to obtain a perfect knowledge of accounts, which many think to be very easy, and, having done that, he considered that he ought to receive some remuneration for his knowledge. He should be very happy to resign the position which he had held amongst them for the last five years if they wished it, but, if re-elected, he was mercenary enough to say that he should only work for pay.

The motion, having been put from the chair, was carried.

The CHAIRMAN then proposed that the auditors receive the same amount as before for their services, which, after a few remarks, was also carried.

The CHAIRMAN having announced that the business of the meeting had concluded,

A vote of thanks to the chairman and directors for the way in which they had conducted the business of the company during the past half-year was carried unanimously, which

The CHAIRMAN briefly acknowledged, and assured the meeting that they would continue to do all in their power for the advancement of the interests of the company.

LAW INTELLIGENCE.

NEWALL v. ELLIOT.—PATENT CASE.—This was an action for the infringement of the plaintiff's patent for an apparatus for laying down submarine electric cables. Mr. Newall, the plaintiff, Mr. Carpmael, the patent agent, and several other witnesses were examined. The plaintiff was a manufacturer of electric cables, having works at Gateshead and a shop in the Strand, and the defendant carried on the same trade at East Greenwich and Great George-street, Westminster. The alleged invention for which a patent was taken out in 1855 consisted of an apparatus for enabling the cable to be laid down quickly, without handling it in the hold of the vessel, and without the risk of its getting into "kinks" or knots. The rope is coiled in an annular chamber, and the outgoing parts pass inside certain rings. The infringement complained of was committed by the defendant in laying down the cable between Malta and Alexandria some time in 1861. An injunction was granted by Vice-Chancellor Wood to restrain the defendant from using a similar apparatus to that of the plaintiff, but it was dissolved by the Lords Justices, and the plaintiff now sought to establish his right to the invention by the verdict of a jury. Mr. Grove, Q.C., in his opening statement, explained that in the first instance the defendant fitted up his vessel with an apparatus nearly identical with the plaintiff's; but before she sailed from England a portion of it was removed, and the infringement of the patent was not actually consummated until she arrived at Malta. The defendant contended, under these circumstances, that the plaintiff could not sue him for the infringement of the letters patent, inasmuch as it took place beyond British dominion. The learned counsel observed that a patent for an improved compass, a new description of rope, or anything else, intended chiefly for nautical purposes, would be useless to the inventor if any person could infringe it on board a British ship as soon as she got beyond our shores. He submitted that as an English ship was British territory, an user of a patent on board, in whatever part of the world she might be, without the sanction of the patentee, amounted to an infringement.—The Lord Chief Baron: Then the infringement turns upon the nationality of the vessel?—Mr. Grove: To some extent.—The Lord Chief Baron: That is a point which I certainly will not decide here. With regard to what you say as to the user of your patent on board a British ship, it may, on the other side, be urged that your claim would have a tendency to give you a monopoly all over the world. For many purposes a British ship is considered to be part of British soil; but my impression is that this doctrine is part of international and not of municipal law.—Mr. Montagu Chambers said that he should contend that the patent in this case, which was granted for Great Britain, Ireland, the Channel Islands, and the Isle of Man, did not extend to Malta, Alexandria, or Australia, so as to make anything done on board the ship there a violation of such patent. He said it was the custom amongst inventors to take out patents, not only for the British Islands, but also for her Majesty's dominions abroad, and for different foreign countries.—The Lord Chief Baron: Your proposition is that if a man made and sold on board a British ship at Melbourne one of Bramah's locks, which is patented here, he would infringe the patent?—Mr. Chambers: Yes; because it is made and sold out of the limits to which the patent extends.—Mr. Grove: I contend that the making of the lock would, under those circumstances, be an infringement, as it was done on board a British ship. There may be a doubt whether the selling would be an infringement.—The Lord Chief Baron: The Australian colonies have legislatures of their own, and may also have their own patent laws.—Mr. Grove: That may be so, but Malta has no patent laws of its own, and it forms parts of the British territory. In this case the infringement we complain of, though commenced in this country, was really consummated on the high seas between Malta and Alexandria. The learned counsel added that the plaintiff instituted a suit in Chancery in 1857 against the defendant for an injunction, and that the whole matter was then referred to Mr. Thomas Webster, the counsel, for arbitration. That learned gentleman made an award substantiating the plaintiff's claim, but he raised certain points of law for the opinion of the Court of Common Pleas. These points were also decided by that Court in favour of the plaintiff. The depositions of Mr. Laws, who was on board the Malacca, one of the vessels employed in laying the cable, and who was now in India, as to the mode of paying out the cable, were put in and read. Mr. Thomas Webster was then examined with respect to what took place before him as arbitrator. The Lord Chief Baron said he should hold with regard to those acts complained of by the plaintiff as an infringement of the patent which were committed out of British territory, that the fact of their being done on board an English ship was of no consequence. The evidence would be taken subject to that ruling, upon which he would give the plaintiff liberty to move the Court above. Mr. Bramwell, the civil engineer of Great George-street, was next called and examined at considerable length in support of the

plaintiff's case. The case, which occupied the Court during the whole of five days, came to a conclusion on Saturday, the 6th inst. The jury found a verdict for the plaintiff, subject to certain points of law, which were reserved for the opinion of the Court above.

The Submarine Telegraph Company *v.* Dickson and others.—The plaintiffs were the owners of the telegraphic cable lying at the bottom of the sea between Dover and Calais. The defendants were shipowners (aliens), and their ship, *Gustaff Adolphe*, while sailing upon the high seas, more than three miles from the English coast, lowered an anchor, and injured the plaintiffs' cable. From the declaration it appeared that the plaintiffs were possessed of a telegraphic cable, which they used for the purpose of transmitting messages between the ports before-mentioned; that the defendants, not regarding their duty whilst the telegraphic cable of the plaintiffs was lying in the high seas, took so little and such bad care of their ship that a cable and an anchor attached thereto were dragged against and caught hold of the said telegraphic cable of the plaintiffs, and dragged, injured, and broke the same, whereby the plaintiffs have been forced to pay the sum of £2,000 in repairing the damage so occasioned; the plaintiffs also lost and were deprived of their telegraphic cable for the space of eighty-one days, and all the profits and advantages which, during that time, they might have derived and acquired from the use of the said telegraphic cable by the sending of messages and otherwise. The defendants said that the said telegraphic cable alleged to have been injured, was lying at the bottom of the sea, more than three marine miles from the sea shore of England, out of and beyond the realm, dominion, sovereignty, and jurisdiction of our lady the Queen, and the said vessel was then also more than three marine miles from the said sea shore, and out of and beyond the said realm, dominion, sovereignty, and jurisdiction respectively, and the defendants then and at the time of the commencement of this suit, were and still are aliens, subjects of the kingdom of Sweden, domiciled in parts beyond the seas, to wit, at Gothenburg, in the said kingdom of Sweden, and subject to the laws of that country, and not to the laws of England, and that the ship was and still is a Swedish and not a British vessel; and the defendants further say that in the usual and ordinary course of navigation, the said ship was proceeding on a voyage from Alicante to Gothenburg, and that upon such voyage, the said ship had occasion to cast anchor, and afterwards had occasion to get up her anchor and proceed on her voyage, and the defendants say that without any default of theirs, the said anchor, after it had been cast as aforesaid, became entangled with the said telegraphic cable, and that in getting up the anchor, in order to save the same, it became necessary to disentangle it from the telegraphic cable, and that part of the said telegraphic cable was necessarily a little dragged and injured; and the defendants further say, that there was no buoy or mark of any kind to show or point out the spot in which the said telegraphic cable was lying, and that before and when the said telegraphic cable so became entangled it was at the bottom of the sea, and incapable of being seen by, and that the place and position and existence thereof was wholly unknown to the defendants and their servants having the management, direction, and control of the said vessel and anchor. The plaintiffs say that before and at the time when the said ship so dragged her anchor, and when the said telegraphic cable became entangled with the said anchor, the defendants and their servants ought to have known, and had the means of knowing the place, position and existence of the said telegraphic cable, and it was through the carelessness, negligence, and want of ordinary or any care of the defendants that the grievances were committed. The plaintiffs also say that one end of the said telegraphic cable was fastened to the soil of the county of Kent, and by virtue of the license, grant, and charter of our lady the Queen, the cable being so fastened, was carried thence across the sea shore of the said county into the sea abutting thereon, and was within three marine miles of the sea shore and coast of the said county of Kent and of the said county, and the said grievances were committed within such three miles as in the first count alleged, and not more from the sea shore of England. Mr. Rochfort Clarke, for the plaintiffs: The defendants show that they were acting with negligence upon the highway of the sea. Persons using a highway must not use it so negligently as to damage anything. Notice is unnecessary. Even where oyster beds are public nuisances, they must not be negligently disturbed. The questions of knowledge and ignorance are matters which must go, with a hundred others, to the jury. The defendants only say that they had no notice of the cable when they cast the anchor. But they may have carelessly allowed the anchor to drag along the bottom, and then carelessly pulled it up.—Mr. Archibald (Mr. Bovill, Q.C., and Mr. Lush, Q.C., with him) for the defendants: The declaration is bad. It is true that it is in the form adopted in collision cases. But this is a novel case, unknown to the code of navigation. It is, therefore, important that the declaration should disclose a clear and imperative duty. All parties who navigate the sea have a right to anchor where the tide turns. Negligence must arise from the breach of some duty, and, unless some duty be shown, the mere averment of negligence goes for nothing. The law as to collisions is an exception to the general principles. In such cases the duty is notorious, and certain regulations are laid down. With regard to the question of jurisdiction, I admit that if a cause of action arise within a country where the claim could not properly be dealt with, this country will deal with it. But that is not so here.—Chief Justice Erle: I think that the declaration is good. Plaintiffs, who are owners of a telegraphic cable, complain of an accident which befel that cable, owing to the negligence of the defendants. I assume, for the purpose of this judgment, that it is lawful to make use of the bottom of the sea for certain purposes. And I think that this Court may take judicial notice of submarine cables. They are named in Acts of Parliament, and are known throughout the world to be lying at the bottom of the sea. In my opinion, therefore, the plaintiffs had a right to use the bottom of the sea, and to place cables there for the purpose of telegraphic communication. The defendants had a right to traverse the sea for the ordinary purposes of navigation; but they carried their rights to excess, so that they came in conflict with those of the defendant. The plaintiffs' property has been damaged, but the defendants say they are not responsible. They say they had a right to the management of their ship, without the control of the plaintiffs. The plaintiffs may answer, true you had that right, but in exercising it you were not to be allowed to harm my cable in a way the contrary of what skill would dictate and due care require. The whole case dwells in that word—negligence. These courts have, then, jurisdiction over the defendants, who have violated the rights of others. Even if they acted in the lawful enjoyment of a right, they acted with negligence. If they had shown due skill, no mischief would have happened. If one person, knowing that another has claims which conflict with his own, carelessly forgets them, he is almost guilty of wilful injury. The declaration, therefore, is good, and the fifth and ninth pleas good. The discussion which has taken place has been a profitable one, as it will put the real question more distinctly before the jury, than would otherwise have been the case. The word "negligence" has a most undefined meaning, it is often as much misapplied as the term "fraud." It is much better that our decision should not turn upon a misapplied term. As for the argument, that the damage arose from the plaintiffs not having placed a buoy over the cable, and that the defendants, without notice, would not be responsible, it cannot be admitted. If there were no notice, a man navigating with due care and skill would not be liable. But the new assignment in effect traverses the plea, and says that there was no due care. If the defendants had no knowledge, at least, they had the means of knowledge, and if the plea be taken away, the declaration and new assignment, when put together, are good. It was said, that if the vessel had been damaged by the cable the owners might have been sued. I think that precisely the same question would then arise as does here. If it were tried the jury would be told to say, whether or not the plaintiffs had laid down buoys with the usual caution, giving other parties the means of avoiding damage. If, according to the mode in which the ship was sailing, she would, in the ordinary course of things, have surely struck against the cable, the plaintiffs would, undoubtedly, have been guilty of negligence.—Justice Williams: I am of the same opinion. I think the declaration good, because it raises the substantial question in the case. As for the new assignment, I must say that to treat it as my Lord does, is rather opposed to my views of the object of a new assignment. But I am willing to treat it as a traverse of the pleas; it will lead to the trial of those facts upon which the issue of the case depends.—Justice Willes: If what took place is assumed to have taken place on the high seas, the plaintiffs may support this action. I was puzzled to find out what the high seas had to do with the question. A vessel must be managed in such a way as that she shall not, by the negligence of her crew, damage the property of others. The mere novelty of the case is nothing, it is only a novelty of circumstances. A steamer going over the bank of Newfoundland may not see the bank, but will run upon it if she does not observe due precaution. Circumstances like these may be taken into account in ascertaining whether there has been negligence, or reasonable care. If an anchor were lying in the highway, and you knew it were there, you might not injure it. So, if any object be mentioned in the charts of the ports which the ship visits, as lying at the bottom of the sea, and if the ship is provided with those charts, or has the means of procuring them, she must do no harm to that object. Such matters must be taken into account by the jury, and cannot be pleaded, so that a question of this kind becomes an inference of fact, and not one of law. If a vessel were improperly anchored at a great distance from another vessel which was approaching, this last one must avoid the other if she can do it with safety. The utmost vigilance, is not, however, called for, if the obstruction be unexpected.—Judgment: That the Court would presume that the masters of ships were aware of the existence and situation of submarine cables, and that a duty was thereby cast upon all such masters of ships to manage their vessels so carefully and skilfully as to avoid (if possible, in the exercise of reasonable precaution) injuring these cables.

New South Wales.—Mr. Cracknell, the superintendent of telegraphs, brought before the Select Committee of the Legislative Council of New South Wales, appointed on the 8th of July last, the subject of connecting with the electric telegraph lines all the lighthouses of the colonies. He considered that the expense would not exceed £5,500. Mr. Cracknell also called the Committee's attention to the applicability of the electric light for lighthouse purposes, having been successfully employed in England, such as at South Foreland and Dungeness; and to the valuable employment of the electric telegraph for meteorological purposes.

CORRESPONDENCE.

THE PNEUMATIC APPARATUS.

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—I beg of you to insert this, my last letter. In your first number it states the pneumatic apparatus had been for many years exclusively adopted by the Submarine Telegraph Company. Mr. Harwood's letter plainly says some were at work when he took charge, but not on all lines.

With respect to the service message of the 9th September, 1863, he sent the only reply a subordinate could forward to his superior officer—had he entered into a discussion it might not have proved very satisfactory to himself. If Mr. Andrews took advantage of his position to represent to the late secretary that the invention of one of his subordinates was his own, your readers will not fail to see such conduct is of a piece with the "I engaged Mr. France," contained in his letter of the 20th ult.

Since Mr. Shaw is quoted I enclose his letter for insertion, and also my instructions to him, for your perusal, in which you will not find the slightest mention of my own name. I fully agree with Mr. Andrews that Mr. Shaw was a most efficient officer, whose services we were loth to lose.

With regard to any letters or service messages about the three other systems, I admit all Mr. A. likes to bring forward. I have not once presumed to judge their respective merits—he undertook that task himself.

What Mr. Guy terms "unfortunate" I conceive, on the contrary, to be the greatest piece of good fortune possible. He says the first pump-relay was not made at the factory at all. The workman he speaks of is Mr. R. B. Jones, electric telegraph machinist, of Nelson-terrace, City-road. The reason I know his name is, that he called on me, in company with Mr. Guy, at the end of 1860, respecting these very relays. I have written to Mr. Jones, and perhaps he will kindly furnish you with the date of the first instrument, without "beating about the bush," as Mr. Guy does. This would settle, once for all, whether any were made before my return from the Mediterranean in February, 1860.

To finish with Mr. Guy's random statements, I never had occasion to have a single pump-relay made, as Mr. Andrews had ordered a sufficient quantity to replace the whole of his No. 3.

I am, Sir, yours very obediently,
J. R. FRANCE.
February 16, 1864. Acting Engineer, Submarine Telegraph Co.

[COPY.]
Cromer Station, January 27th, 1861.

J. R. France, Esq., Engineer.

Dear Sir,—I have carefully watched the working of your pump-relay, during the past week, and have much pleasure to report its complete success. I find that, by the aid of the spiral-regulating spring, Flensburg is enabled to interrupt London in the middle of a word, without waiting for more than the ordinary pause; and, from the great reduction of connections and contract-points, there are less chances of local faults occurring.

Taking these things into a little consideration, with the decrease of expenses for local batteries, I would respectfully suggest the same system on all Danish lines.

I am, yours very obediently,
(Signed) W. H. SHAW,
Clerk in charge.

To the Editor of the TELEGRAPHIC JOURNAL.

Sir.—In accordance with Mr. France's request, and with all due respect to both gentlemen concerned in the dispute, I furnish you with the date, by referring to my books, and find I made the first pump relay on the 27th of November, 1860.

I am, Sir, your obedient servant,
R. B. JONES.
Nelson-terrace, City-road,
Feb. 17, 1864.

[Since the above was in type, we have received a letter from Mr. Jones, in which he states that he was in error as to the date, it being the 27th October instead of the 27th November.—This discussion must terminate next week.—ED. T. J.]

[ERRATUM.—In Mr. Bordeaux's letter, which appeared in No. 7, page 83, instead of "for *multiplying* the effects of, &c.," read, "for nullifying the effects of return current."]

A SUGGESTION.

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—The invitation of your correspondent "H. ELP" to your subscribers and readers to assist in the manner he proposes to make your Journal what its title implies it to be, will I trust meet acceptation. I now and then glance over the pages of the *Civil Service Gazette*, which bear evidence of co-operation on the part of its subscribers and readers in furnishing news, &c., from their respective localities. Brief notices of meetings, appointments, improvements, &c., would greatly contribute to increase the usefulness and popularity of the Journal.

10th February. D. P.

TELEGRAPHIC FEATS.

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—A "Bell Clerk" says he is surprised at the transmission of Mr. Bright's speech, as remarked upon in your columns, being called a telegraphic feat. Before proceeding further, I fully endorse that opinion; it is indeed a poor speed, "even for the Morse." The Morse instrument must, however, be taken upon its several merits—not only its rate of speed, although that is by no means to be despised. I will undertake to find at any moment a clerk who will transmit a speech or lengthy communication that will be *recorded*, and can consequently be referred to at any future time in case of necessity, at a uniform rate of thirty words per minute, and am persuaded some five or six words more might be added; but it is always advisable to keep within limits, and not make an assertion based upon imagination. The other advantages are numerous. Will the "Bell Clerk" undertake to say he never feels doubtful respecting the correctness of a word in any message he may have received? If he does not feel certain, either the word must be repeated—which repetition takes a considerable portion of the time that would be occupied in receiving another message—or he must *chance*, perhaps, the most important word in an important message being correctly rendered. With the Morse, however, the clerk can look carefully at the word, providing there is any doubt, or the band can be again read over by a disengaged clerk while the other is going on with his duty—another advantage. About seven years ago, when we were not thoroughly experienced in working the Morse, and the instruments were not nearly as perfect as they are now, I recollect the Emperor's speech (in French) being transmitted by a French clerk who did not understand English, and received by an English clerk who did not understand French, at a uniform rate of nineteen words per minute. Giving every credit to the Bells, I doubt whether two English clerks could do this even at the present day. In corresponding, as merchants often do, by cypher, or transmitting messages in foreign languages, and in general correctness, the Morse excels all systems now in use; even in speed, for one, I will not yet yield the palm, taking the ordinary working speed. At one time I used to argue that there is nothing like the double needle; but from experience I say the double needle, although it should ever be remembered as the first instrument to render telegraphy available for general use, ought, with every consideration and regard to the present advanced systems, to be an obsolete instrument. In the first place, there are two wires required for one circuit, consequently the outlay in providing communications is very great, in fact double that required for a single-wire telegraph. Secondly, it is scarcely possible for a clerk to read and write at the same time. The eyes have quite enough to do to follow the motions of the two needles, especially if a great speed is maintained. Again, in cases of contact, the single needle must be resorted to, and clerks working the double needle have little practice in single needle working. On a line where the traffic is great, a contact means very nearly a break down. Upon single-needle circuits, when a contact occurs between two wires, the means of communication is immediately halved; but it is far more than halved with the double needle for the reasons just stated. If needle instruments are adhered to, the Magnetic Company's is undoubtedly the best; but as that requires a writer, the Bells then are much better; consequently, it appears evident the real contest is between the Bells and Morse. If properly worked by efficient clerks, the Morse will be found the speediest, most correct, and the most easily worked system in present use. It is more than likely the Electric Company, who still use the double needle on some lines, are possessed of clerks who, from want of practice, are not yet proficient in Morse working, at least so the telegraphic feat seems to suggest.

I am, Sir, your obedient servant,
AN OLD DOUBLE NEEDLE AND MORSE CLERK.
Dover, 9th Feb., 1864.

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—Although unconnected with telegraphy as a science or profession, I feel greatly interested in its progress as one deriving considerable advantages from its powers of transmitting intelligence with marvellous expedition and certainty, and would feel exceedingly obliged to you, or any of your readers, if you or they were to explain in your columns how is it that so much difference exists as to the time occupied by the various companies in the transmission of long speeches, as evidenced in the Birmingham and Queen's speeches. It appears from your Journal of the 30th January that the Electric and International Telegraph Company transmitted the Birmingham speeches to London in about five and a half hours, or at the rate of thirteen words per minute. The Magnetic Telegraph Company and staff allege that they transmitted the same matter at the rate of thirty words per minute, and the United Kingdom Telegraph Company accomplished the same work in less than four hours. Again, with respect to Her Majesty's speech, the Electric and International Telegraph Company are represented to have transmitted the speech to several places at the rate of thirty-five words per minute, the Magnetic Telegraph Company at the rate of forty-eight words per minute, and the Submarine Telegraph Company at the rate of less than nine words per wire (five being employed) per minute. It would be very interesting to know the reason why such difference exists in the power of transmission.

Renfrew. P. D. MAXWELL.

SELF-HELP.

To the Editor of the Telegraphic Journal.

Sir,—The remarks of "Amicus" in your impression of the 6th instant are very just, and to the point, when he asserts that the want of self-help is the reason of the subordinate position telegraph clerks occupy, both in society and in literary acquirements.

I have frequently thought that a Literary and Scientific Institution, common to the employés of the various telegraph companies, would exert a great influence for good. I am convinced, if the clerks showed themselves anxious to form such a society, they would secure the support of the various directors in the undertaking, as any scheme having for its object the intellectual improvement of their employés, would naturally claim the sympathy of the shareholders. In conversation with a gentleman, some days ago, I was told that no society—whether for mental improvement, bodily recreation, or pecuniary benefit—formed in connection with telegraph employés, had ever succeeded. I could not contradict his remark, as my experience in the profession was somewhat limited. But when I looked around me, and saw none existing—or, at all events, flourishing—I thought there was some foundation of truth in his assertion. And why should it be so? Other professions have their literary and scientific institutions, and their clubs for recreation—warehousemen, commercial and legal clerks, have each specific societies of this nature, and I think I am by no means presumptuous when I state that, by co-operation and perseverance, we may be able to raise ourselves and our profession to the same level as the other and more flourishing bodies of clerks. But to obtain this result, we must work together harmoniously and methodically, with a single end in view—our mutual welfare: mind, work together—not singly, each by himself, but in thorough, earnest union. A man by himself is a cypher: it is only when he takes his place as a unit in society, that he becomes of value to himself and his fellow men. There is much philosophy in the divine precept, "Bear one another's burdens." For in elevating and promoting the prosperity of those around us, we secure, in like proportion, our own advancement and happiness. A Provident Society for Telegraph Clerks generally has recently been established, and which I earnestly hope will succeed in its objects. One or two institutions of a conservative nature have been formed, in connection with the various companies, for mutual instruction and amusement; but, to meet our requirements, we must have a General Institution, Library, and Club, for all classes of telegraph clerks, irrespective of company. I should like to know the opinions of my fellow employés upon this subject, through the medium of your valuable Journal; and I think, Mr. Editor, it would prove of material assistance to have a few hints from yourself on the best means of promoting the social union and prosperity of the telegraph clerks, of whom I am One of the Least.

RAILWAY TRAIN SIGNALLING.

To the Editor of the Telegraphic Journal.

Sir,—Only that your correspondent, "J. L. Martin," under the above head, adverts to the necessity of a communication between guard and engine-driver, I feared the subject had become a thing of the past—for it is only at the moment we are in imminent danger that we resolve to remedy the future. The powerful arm of the press seems to have achieved but little towards the consummation of this all-important requirement. Though the President of the Board of Trade has asserted that it is a "subject worthy of consideration," yet the different railway companies turn a deaf ear, and will continue on, in their accustomed "penny-wise and pound-foolish" way of doing business. Perhaps, if blood is really shed, railway companies may be again awakened to the necessity of there being some effective "communication" adopted; and, unless the press keeps the subject alive, they will dose off again, only to be aroused by something more serious, if not to them in a pecuniary point of view, to the railway traveller, who, it seems, is to have no remedy, save in case of accident, from the valuable insurance companies. There is not the slightest doubt but that railway travelling has become a terror to most people, and especially to the weaker sex, who avoid travelling alone. What a boon and comfort it would be for railway travellers to know, that where life is in danger, through fire, &c., or when a criminal assault is made, merely the raising of the hand to the roof of the carriage would call the attention of the official in charge of the train. I am convinced that was there a "communication" fixed in every carriage, with instructions as to its use, as well as a quotation from railway bye-laws as to the penalty for abusing it, it would scarcely ever be used (especially in indecent assaults), as the fear of it would deter even the most evil-disposed. "A maniac might misuse it, but the very act would lead to his being secured; and an all-sufficient check upon mischief-making frolic might easily be obtained in a fine commensurate with the real cost of such diversions." It is certainly loneliness that tempts people to make the very numerous attacks upon defenceless females. Adopt some system of "communication," and the temptation becomes removed.

That there are infallible systems of train communication, both electrical and mechanical, in the hands of inventors, is certain—only waiting the time when railway companies shall be convinced that something must be done.

The general recommendation is, that "communication between passenger and guard" is what is wanted; but, for my part, I cannot see the utility of it: for, supposing the passenger communicates with the guard, what assistance can be rendered, without stopping the train? I maintain that a communication between passenger, or guard and engine-driver, is the only thing needful.

Evidently, the real question is one of expense; but would not the outlay soon be repaid? Doubtless, the increase in the receipts would quickly show itself—as the moment safety is secured, the number of travellers will be augmented. Husbands cannot always leave business to travel with their wives; neither can fathers always accompany their daughters. Let it once be certain that aid can be summoned when required, and railway travelling will no longer be dreaded.

Apologising for trespassing so far upon your space, and trusting that the matter will be kept alive, I am, Sir, your obedient servant,

Chester, Feb. 16th, 1864. Fiat.

TELEGRAPHIC NEWS.

We are glad to find that Mr. H. Moor, Chairman of the Mediterranean Extension Telegraph Company, has been returned to serve in Parliament for Brighton.

The venerable Mrs. Somerville, now in her 82nd year, well-known for her valuable work on the *Physical Sciences*, is now engaged in preparing for the press a new edition of the same. Telegraphists owe much to the esteemed authoress. Mr. Fothergil Cooke, some twenty-five years ago, wrote—"The first idea of my mechanical telegraph suggested itself to my mind, on the 17th March, 1836, during my journey from Heidelberg to Frankfort, when reading Mrs. Somerville's work on the *Physical Sciences*."

The Persian Gulf Cable.—Intelligence has been received that two of the vessels, having on board portions of the above cable, had left Bombay for the Gulf; and information is daily expected of the successful submersion of the section, and of the arrival at Bombay of the vessels with the remainder of the cable.

The Great Eastern.—We are informed that negotiations are in progress with the Great Eastern Steamship Company (Limited) for the employment of the ship in the laying of the Atlantic telegraph cable. The ship is admirably adapted for such a service, as from her great length there is an entire absence of pitching. The terms of the proposed charter are highly favourable, and will not only yield a handsome dividend to the proprietors, but leave such a surplus as will refit the ship at the termination of the engagement for any employment which may be determined on.

Magnetic Telegraph Company.—A numerously-attended meeting of the London *employés* of this company was held at their Central Station, 58, Threadneedle-street, on Saturday evening last; Mr. G. C. Newbury, Station Superintendent, in the chair. After a spirited discussion upon the approaching annual picnic and pedestrian handicap, which is arranged to take place in June next, the Chairman called the attention of the meeting to a letter he had received from Miss Oppenheim, Secretary of the Telegraph Clerks' Provident Fund, asking him to solicit the clerks to become members of the said fund. Before doing so he had thought it necessary to carefully study the rules, &c., and, having done so, would now read them, so that the clerks present could discuss their merits or demerits, and come to a conclusion whether they intended joining or not. An animated discussion then ensued, ably sustained by Messrs. Manning, Wild, Stannard, Randolph, and Harper, the meeting finally passing the following resolution:—"After carefully investigating the scales of payment, remuneration, and the rules, regulations, &c., of the 'Telegraph Clerks' Provident Fund,' this meeting is of opinion that the benefits to be derived therefrom are not adequate to those offered by other societies of a like nature, and that the numerous technicalities and requisitions introduced into the said rules debar the majority of telegraph clerks from becoming members." In proposing the health of Mr. Edward Bright, Secretary to the Company, the Chairman said he was happy to inform the meeting of the daily increasing strength and recovery of Mr. Bright, who he was sure was held in the highest esteem, whose illness was watched with the keenest anxiety by all who knew him, and than whom a better secretary could not be found. The toast was drank with loud applause, and the following resolution, proposed by Mr. Randolph, carried amid great enthusiasm, a copy being sent to Mr. Bright:—"That this meeting receives with hearty gratification and pleasure the announcement of Mr. Edward Bright's return to convalescence after so severe an attack of illness, which nearly deprived them of the services of a highly-esteemed and respected secretary; they, therefore, beg most respectfully to offer to him their sincere congratulations upon his recovery, and trust he may long be spared to perform, as ably as heretofore, the duties of Secretary to the Magnetic Telegraph Company." A vote of thanks was warmly accorded to the Chairman, who, in responding, expressed his entire satisfaction at the manner in which the duties of the office had been performed since his accession to the superintendency, and hoped the clerks would continue to uphold the friendship and unity already existing amongst them, which would tend greatly to the successful working of the company's business. The proceedings then terminated. A Discussion and Elocution Class is about to be formed, for which purpose a meeting will shortly be held.

TELEGRAPH COMPANIES.—Numerous complaints have reached the Council of the Huddersfield Chamber of Commerce during the year, as to the errors and omissions in the telegraphic intelligence supplied to this Chamber. The Council entered into correspondence with the Electric Telegraph Company upon the subject, and Mr. C. H. Jones and Mr. Wrigley, as a deputation from the Council, obtained an interview with the company's manager, at Manchester, and succeeded in procuring certain alterations and improvements in the existing arrangements, without additional cost to the Chamber, and which, it is hoped, will place this department on a more satisfactory footing for the future. The Council have also addressed a communication to the United Kingdom Telegraph Company, enquiring when its system of wires would be extended to Huddersfield, so as to make available the cheap telegraphy promised when the support of the Council to their Act of Incorporation was obtained. In reply to this communication the Council have received the assurance that the works of the company are being rapidly completed.

CHIMNEY SHAFT LINES.—We have received information that the United Kingdom Telegraph Company have completed their line to Huddersfield, and a great saving has been effected in house-top work, erection of poles, &c., by carrying the wires through the town on insulators, fastened to brackets inserted in the numerous chimney shafts which abound in the district. An accident, however, occurred before the completion of the work, involving the company in no inconsiderable amount of expense. The contractor, while fixing his ascending tackle to one of the shafts, pulled a large stone from the top which, in its descent, did great damage.

TELEGRAPHIC SIGNALS FOR RAILWAYS.—A very interesting display of various descriptions of electric telegraph apparatus was made at a *conversazione* held at Brighton on the 5th inst. Messrs. Silver & Co. exhibited, among other things, an improved (Ragon's) call-bell. The apparatus is an admirable improvement on the old clock-work alarum, hitherto the only one in use for long circuits, the mechanical arrangements of which were constantly getting out of order. The Ragon's, on the contrary, has no wheel-work, and, therefore, requires no winding up; will ring from any distance, and continue ringing till call is answered—a great desideratum in the electric and railway world. They are in use by railway and telegraphic companies both in England and on the Continent. The electric semaphore instrument, used on the South-Western; the block-over-needle instrument, used on the North-Western, &c.; the needle and bell instrument, used on the London and Brighton Railway, were also shown; this instrument combines efficiency with great simplicity of working, as by a single movement of the handle a current is transmitted through an electro-magnet, which deflects a magnetised needle suspended between the poles, and actuates a rack and pinion, on which is fixed a pointer or indicator that rests on either side of the dial, having the words "clear" and "closed" painted on it; thus, when a train leaves a station the indicator on the instrument at the next station is put over to the word "closed." The current at the same time attracts an armature suspended in front of the magnet, having a stem and knob fixed to it, which strikes a single blow on a ball or gong suspended in the instrument, thus giving notice that a train is on the line between the two stations. This signal is replied to in the same manner, by the signal-man giving one or more blows on the bell or gong of the instrument that sent the signal, by which means each station or signal-box is made aware if the line is clear or closed, as the pointer, once put over, remains so till the opposite signal is sent. Another feature is, that any number of blows can be given on bell or gong without working the needle; thus, any kind of signal can be sent according to a preconcerted code, as three blows for a Brighton train out, and so on. Mr. Funnel, of Brighton, also showed a working model of his patent electric signal-post, which is worked by the passing train putting the signal on and taking it off at any required distance; this is effected by the electric current acting on a train of wheels inclosed in the post, and in connection with the semaphore arm, which it raises or drops. Mr. Funnel proposes to have the clock-work to run a certain length of time, and the posts to be placed at certain distances from each other, by which means the driver or guard of any train will know the exact position of the train ahead. One of these posts is now worked near the Brighton terminus of the railway.

THE INTERNATIONAL PACIFIC RAILWAY AND TELEGRAPH.—The following letter has appeared in the *St. Paul's Press*:—"Grand Trunk Railway of Canada, Managing Director's Office, Montreal, December 24, 1863. My Dear Sir,—I returned from England about a week ago, where I have been for the last two months. . . . . . I have no doubt whatever that the line of telegraph will be completed from St. Paul to Fort Garry, and thence across the Hudson's Bay territory to the Rocky Mountains, and thence to the Pacific. I think I am also safe in saying that negotiations, which are now in progress, with reference to the continuation of the line of railway from St. Paul northwards to Fort Garry, will result in the actual construction of that line of railway before very long, and that steps will immediately be taken to continue the line across to the Pacific coast. I find very great interest existing in London about the Hudson's Bay Company, a line of telegraph, and a waggon road, and, ultimately, a railway; and I have no doubt of the accomplishment, at no very distant date, of these important enterprises. Whilst I was in London I had an interview with his Excellency General Guerbard, who is the Director-General in Russia of the telegraph system of that country. From him I learned many important facts connected with the telegraphic enterprise across Siberia, and found that the construction of the telegraph to the mouth of the Amoor River was a matter not only absolutely decided upon, but in active progress at the present moment. The General appeared to be quite convinced of the probability of the line being continued from the Amoor River, by way of Behring's Straits, to the borders of British Columbia; and, from the information which I have derived from him, I do not think we shall have as much difficulty or anything like it in connecting St. Paul, by way of the Hudson's Bay territory and the Rocky Mountains, with the northern boundary of British Columbia, as the Russian Government have experienced in the lines of telegraph which they have made across Siberia. Yours very truly, C. J. BRYDGES.—J. W. Taylor, Esq., St. Paul."

AUSTRALIAN TELEGRAPHS.—We quote the following intelligence from the *Sydney Morning Herald*, of the 21st December, ult.:—"All the more important towns in the colony being connected with Sydney by the telegraph, there are few works in progress for the extension of telegraphic communication, and the lines now proposed are mostly those the interest of the cost of which is guaranteed to the Government, by the residents in the districts through which they are to pass. A second wire, between Sydney and Newcastle, upon the old posts, has been completed and brought into use during the last month. The line connects Windsor, Wollocombe, West Maitland, Morpeth, and Newcastle, with the metropolis, by a separate circuit. For the old line, a submarine cable was laid across the Hawkesbury, but the two wires are now stretched between masts 100 feet high above the river, the distance between the masts being about one-third of a mile. The cable is, however, still available in the event of the other wires not being found to answer. Upon the extension from Deniliquin to Hay, the wire is stretched as far as Conago, twenty miles from Deniliquin, and the poles are up for a distance of twelve miles beyond. Arrangements have been made for continuing the wire from Braidwood to Queanbeyan, and the contract for the work has been taken by J. Murphy, Esq., to be completed in three months. The extensions proposed, in the estimates for 1864, are from Mudgee to Murrandi; from Brardwood to Morruya, *viâ* Arulen; and from Kindra to Cooma. In the supplemental estimates for 1863, there is a sum proposed for a private line to Mimi, a distance of six miles.

MISCELLANEA.

SELF-CULTURE.—The education received at school and college is but a beginning, and is mainly valuable in so far as it trains us in the habit of continuous application, and facilitates self-education after a definite plan and system. To enable the mind freely to exercise its powers, it is necessary, even under the most thorough system of culture, that there should be occasional gaps for its free operation. Thus left in some measure to find out what it can do, and what it cannot do, it will gain in strength and activity, and the evils arising from a too entire dependence on the teaching of others will be in a great degree avoided. Often the best education of a man is that which he gives himself, while engaged in the active pursuits of practical life. Putting ideas into one's head will do the head no good, no more than putting things into a bag, unless it re-act upon them, make them its own, and turn them to account. "It is not enough," said John Locke, "to cram ourselves with a great load of collections; unless we chew them over again, they will not give us strength and nourishment." That which is put into us by others is always far less ours than that which we acquire by our own diligent and persevering effort. Knowledge conquered by labour becomes a possession—a property entirely our own. A great vividness and permanency of impression is secured; and facts thus acquired become registered in the mind in a way that mere imparted information can never produce. This kind of self-culture also calls forth power and cultivates strength. The self-solution of one problem helps the mastery of another; and thus knowledge is carried into faculty. Our own active effort is the essential thing; and no facilities, no books, no teachers, no amount of lessons learnt by rote, will enable us to dispense with it. Such a spirit infused into self-culture gives birth to a living teaching, which inspires with purpose the whole man—impressing a distinct stamp upon the mind, and actively promoting the formation of principles and habitudes of conduct.

THE following Table, by Professor Mathiessen, F.R.S., shows the conducting-power of some of the pure metals, thus:—

	Conducting power at 0°.
Silver (hard drawn)	100·00
Copper "	99·95
Gold "	77·96
Zinc	29·02
Cadmium	23·72
Cobalt*	17·22
Iron*	16·81
Nickel*	13·11
Tin	12·36
Thallium	9·16
Lead	8·32
Arsenic	4·76
Antimony	4·62
Bismuth	1·245

* Probable value for the pure metal deduced from the observations with the impure one.

The First Practical Introduction of the Electric Telegraph.—It has generally been received as a fact that the electric telegraph owes its first practical introduction as a medium of communication to its having been the means of the capture of the murderer Tawell on the 1st of January, 1845. We are in a position to prove that its extraordinary capabilities were practically exemplified under more favourable and pleasing auspices. An original document now lies before us, a copy of which appeared in the *Times* on the 15th of April, 1844 :—"The first intelligence of the arrival of His Royal Highness Prince Albert in this country from Germany, on Thursday last, was communicated to Her Majesty at Windsor Castle by means of the galvanic telegraph on the line of the Great Western Railway. Within one minute of the arrival of His Royal Highness at the Paddington terminus the information had reached Slough, at which station a special messenger, mounted upon one of the fleetest horses in the Royal stables, was stationed by command of the Queen, and who proceeded with the gratifying intelligence to the Castle, where he arrived in eight minutes and a half from the time of his leaving Slough. Thus the news of the Prince Consort's return to England reached Her Majesty and their Majesties the King and Queen of the Belgians in less than ten minutes after His Royal Highness had arrived at Paddington, and forty minutes before the Prince had reached the Royal residence at Windsor." Its great practical value was, however, permanently established as a "means of communication between distant places," by the successful transmission of Her Majesty's Speech in the month of February, 1845, from London to Portsmouth.

Application of the Electric Telegraph suggested in 1836.—The cases in which the convenience of individuals would be affected are innumerable ; and perhaps there are few persons, however generally unconnected with the transactions of the busy world, who would not sometimes be spared either a lengthened epistolary correspondence or an expensive journey, by a few short communications through the telegraph. The comfort of friends and relations, far distant from each other, would often be materially involved, especially in cases of sickness ; and it may not be too much entering into detail to specify that particular instance, where sickness appears hastening towards a fatal termination with such rapidity that a final meeting is without the range of ordinary means. Though the application of the telegraph to private affairs is less dazzling than that to Government and commerce, it is perhaps not less intrinsically valuable, as equally tending towards the one and only justifiable object of all establishments—the aggregate of comfort and happiness to the nation. It may here be observed, that should it at any time be desirable for the Admiralty, in their communications with vessels lying off telegraph ports, to convey their dispatches direct during the night, the apparatus in ordinary use, conveniently situated facing the sea, may, by a peculiar adaptation of the hydro-oxide lime burner, arranged for this instrument, extend their correspondence many miles across the water. Even His Majesty's navy might be furnished with instruments of a simpler arrangement than that proposed for land service, to communicate signals during the night, the action of which would not be interrupted by the motion of the vessel during bad weather. For short distances of a few miles, a powerful argand lamp would answer this purpose effectually.—*Mr. Fothergill Cooke's Pamphlet.*

RECENT PATENTS:

1620. William Andrews, of 237, Gresham House, Old Broad-street, London, "Improvements in Apparatus for Insulating Electric Telegraph Wires." Dated 29th June, 1863.

This invention has for its object improvements in apparatus for insulating electric telegraph wires. For these purposes, in addition to the ordinary insulating apparatus or instruments used for supporting electric telegraph wires, the arms and brackets at the parts where such insulating apparatus or instruments are applied are kept free from moisture by a peculiar construction and application of sheds or covers, which are open at the bottom. When projecting arms are used fixed to uprights, the outer ends of such arms, where the ordinary insulators for supporting the wires are applied, have inverted box-like sheds applied. These sheds are made of glazed earthenware or other suitable material ; they are closed at top, at the two sides, and at the outer ends, and such sides and ends descend below the under surfaces of the arms. The sides, ends, and tops of these sheds do not come in contact with the arms, but narrow spaces are left between the inner surfaces of the sheds and the outer surfaces of those parts of the arms where such covering sheds are applied. The inner ends of the sheds are either open or partially closed, and grooves or recesses are made all round the arms where the inner ends of the covering sheds come ; hence, any rain or moisture which may fall on the other parts of the arms beyond where the covering sheds are applied will be prevented flowing or passing to the outer ends of the arms over which the covering sheds are applied. When brackets are used, and the outer ends thereof rise above the level of the inner parts of the brackets, then the covering sheds come all round the outermost ends of the brackets, but the sheds are open at bottom. When the wires are supported by insulating instruments or apparatus above the arms, then the bolts or pins, on which the supporting insulators or instruments are received, pass through the upper parts of the inverted sheds into the arms, and such bolts or pins are coated with insulating materials, or they are otherwise well insulated.

TO CORRESPONDENTS.

J. C. L. is thanked for his communication. The subject referred to will receive our best attention.

H. D.—The following books will be especially serviceable to you :—"Bond's Handbook of the Telegraph," "Ganot's Elementary Treatise on Physics," Miller's "Elements of Chemistry and Physics," vol. i., and "Stockhardt's Rudiments of Chemistry." London : J. Spon & Co., Bucklersbury.

As information respecting Improvements, Extension of Lines, and Progress of New Undertakings will at all times be most acceptable, we hope that our readers will kindly render us assistance in our efforts to establish a Journal worthy in all respects of the great interest it seeks to represent, by furnishing us with brief notices of events and occurrences in connection with Telegraphy.

Communications intended for publication must be authenticated by the names and addresses of the writers; not neccessarily for insertion.

Letters relating to Advertisements are to be addressed to the Publishers. All other letters and communications to be addressed to the Editor of the *Telegraphic Journal*, 5, Suffolk-lane, Cannon-street, London, E.C.

The *Telegraphic Journal* can be had of Messrs. Smith & Co., Strand ; Messrs. Dawson & Co., Cannon-street, E.C. ; Messrs. Kent & Co., Paternoster-row, London. Messrs. Heywood & Co., Manchester ; at the various railway stations ; and of all news-agents, &c., &c. ; or it can be supplied, if preferred, direct from the Office on the following terms :—

	s.	d.
Quarterly	4	4
Half-yearly	8	8
Yearly	17	4

TO ADVERTISERS.

The *Telegraphic Journal* is the most effective medium for inventors, patentees, contractors, manufacturers of insulating materials and electrical apparatus to submit their various specialities to the consideration of secretaries and managers of telegraph or railway companies, and other persons engaged in electrical and telegraphic pursuits.

Clerks, assistants, manipulators, and instrument makers, seeking employment, &c., will find the *Telegraphic Journal* a ready means of making known their requirements.

Advertisements must be delivered to ensure insertion before Seven o'Clock on Thursday evening in each week. The charges for Advertisements are—

	£.	s.	d.
Whole page	4	4	0
Half ditto	2	10	0
Quarter ditto	1	7	6
Four lines and under (single column)............	0	3	6

Single Advertisements from the country must be accompanied with stamps in payment.

INDIAN TELEGRAPHY.

THE introduction of the electric telegraph into British India, by Sir W. O. S. Brooke, F.R.S., has conferred upon that vast empire advantages of the highest importance, both in a social, commercial, and political point of view. In conducting the affairs of a country where the principal seats of government are so far asunder, the possession of an instantaneous means of communication must at all times be exceedingly valuable. Sir William, in his last Report on the Electric Telegraph in India, previously to his departure for Europe, in 1861, on medical certificate, gives a most interesting account of the extent and the general working of the system. At that period, there were 10,994 miles of telegraph, and 136 offices open for public correspondence. Several offices had been closed during the year, as no longer necessary for military or public purposes. The rapid decay of the timber-posts was the source of much trouble and expense,—the mean duration of such supports being about five years,—and measures were in progress for the supply of iron standards, for all India, of which 40,000 had already been erected, and which had given the utmost satisfaction. The earthenware insulators, however, caused much annoyance and many interruptions—continually breaking, from their weakness and brittleness. The instrument employed was that of Morse, and the signals, in most cases, were read from sound, as long has been the case in America. The total number of private messages sent in all India, Pegu, and Ceylon, in 1858-59, was 101,164; and in 1859-60, 170,566; of service-messages in the same periods respectively, 56,670 and 31,868 — showing that a reduction in the number of the latter had been satisfactorily effected, while an increase in the former of 68·61 per cent. had taken place. The value of the service-messages was, in 1858-59, 3.64.739 rupees; in 1859-60, 1.20.169 rupees. The number of messages sent by *native* merchants and correspondents, during the two years was—in 1858-59, 39,724; in 1859-60, 71,544. This increase was considered very important, as the European community was comparatively small, and might not be capable of affording a very large increase of business. The native bankers and merchants, and community generally, could give as much work as the lines could ever perform. The telegraph staff of India, at the same period, consisted of one chief superintendent, three divisional superintendents, nine deputy superintendents of circles, and upwards of 1,100 inspectors, assistants in charge of offices, signallers, probationers, accountants, clerks, writers, &c., exclusive of line and cable guards, and office servants of all kinds. The difficulties which the Director-General of Telegraphs in India had to contend against in the management of a staff so numerous and so widely dispersed over the country were very great.

In speaking of the progress of the lines, he observes, that great reductions will be practicable in the number of the employés as fast as iron posts were provided for the lines, as one-half of the establishment of line-inspectors, artificers, and overseers, and several hundred of line guards and mounted patrols, would be discharged, at an estimated saving of 40,000 rupees per month on establishment only, and further adds, "a great number of accountants, clerks, and writers, might be discharged at once, with much advantage to the public service. Half of them are worse than useless, but the difficulty of getting rid of these persons is very great. They fasten upon public departments with a tenacity inspired by the enjoyment of sinecures and the prospect of pensions. To attempt to dislodge them is followed by appeals to Government and outcries about cruelty and persecution, so that the reformer and economist soon finds himself an object of popular execration. All this is very disagreeable, but the duty must still be performed." It appears that the total cost of the establishment for all persons drawing more than ten rupees per month, amounted to 68,310 rupees, and the house-rent, the Bengalore workshop, line and cable guards and peons, including the salaries and wages, amounted to 88,121 rupees. The total expenditure of the department for the financial year 1859-60, exceeded 17.20.427 rupees, included the expense of the construction of several new lines.

Sir William concludes his interesting report in the following emphatic words :—"There is a great future before the Telegraph in India. By perseverance and determination it should be made the best in the world, inasmuch as it possesses an unity of organization unattainable elsewhere, with all the resources of the empire to promote its extension and improvement. In two, or at most three years from this time, the lines should yield a clear profit, and an uniform minimum charge for messages may then be adopted for all India. This, with the general use of some simple cypher by habitual correspondents, will enable the Telegraph to perform much of the present business of the post-office. Meanwhile, we have at our disposal, at a moderate cost, an instrument of such miraculous power that, by a single message, it has already saved our Indian Empire; while day by day, and hour by hour, it is busy in the promotion of commerce and the furtherance of private interest of every kind. In my extended tours over all parts of India I have seldom met a family who had not some anecdote to tell of the services the Telegraph had done them. There are few Europeans in India who have not experienced a thrill of pleasure when they meet our masts and wires on the margin of every road, and know that these true tokens of science, and civilization, and power, traverse our Indian Empire to its utmost limit. Should I see them no more, I can truly say that I shall ever continue to take the most heartfelt interest in the prosperity and improvement of the department, and feel proud and happy that it has been my lot to bring it even to its present imperfect state."

However, India is still inadequately supplied with Telegraphic communication, although the Government has made great progress in extending its lines. The commercial community is anxious and ready to support any well-organized system, such as the one now proposed, which is to be similar in its constitution to the Telegraph Companies of England, and to be carried out by the Oriental Telegraph Company, which proposes to commence its lines at Kurrachee upon the completion of the Persian Gulf line, and working from thence towards Bombay, Calcutta, and other important cities in India.

A PLEA FOR THE CLERK.

CARLYLE, in one of his brilliant essays, affirms that "labour is worship;" and other authors, distinguished for the elegance rather than the utility of their productions, are frequently pleased to expatiate upon "the dignity of labour"—a piece of sentimental phraseology which might serve as a keynote to suggestive argument, but which is more often used to minister

to a very general vanity, leading the reader to a conception of his own superlative merit, and society's incapacity to appreciate talent. To these rhapsodies we attach but little importance. We desire to be eminently practical, and, of course, can only be suggestive. It will be readily conceded that every man, who faithfully labours in the sphere in which he finds himself, is entitled to the respect and consideration of those who occupy more exalted and influential positions; and this is what we claim for the clerk. It is only to be expected that gentlemen who invest capital largely in telegraphic enterprises should look for some return; but we insist that the system of grinding down the employés of public companies, in order to realise dividends for shareholders, is a very questionable proceeding, which will be sure to entail evil consequences.

Those who are at the present time engaged as instrument clerks are generally well-educated, are expected to maintain a decent exterior, and to devote themselves exclusively to the service of the company by whom they are employed; the consequences of any breach of confidence, by those who are entrusted with the secrets of the cabinet, the interests of all our banking concerns, and the commercial transactions of the country generally, cannot be estimated. But what will be thought of the remuneration received for the fulfilment of these requirements, when we reveal the fact that they do not receive more than from 16s. to 25s. per week. Artizans combine to represent the insufficiency of their wages, and sometimes make demands which few employers can concede—a reprehensible proceeding, but one which enables them to make known their grievances. Now, the telegraph clerk has not, from the isolated nature of his occupation, opportunity or means of communication with his fellows, whereby he may be enabled to effect improvements in his condition, but is under the necessity of living and bearing with his miserable pittance. Granted that opportunities are often presented, which enable the diligent and persevering among them to rise from the ranks. It is not individual advancement that is needed so much as a generally commensurate payment for services rendered. We have received so many communications from all parts of the kingdom, enquiring, "Can't you do something for us poor clerks?" "Would it be out of your power to direct the attention of shareholders to the illiberal wage paid to instrument clerks?" &c., that we are persuaded there is something wrong in the working of our telegraph system, or complaints would not be so general.

Here is a large class of educated, respectable persons, without any means of association for mutual protection, complaining of their inadequate pay. What is be done with them? The counsel of our Foreign Secretary, "rest and be thankful," is a very good general recommendation, but is a mockery when given to underpaid servants. It is useless to advise a study of the principles of political economy as a means of reconciling them to their position. Political economy is, unquestionably, against them, and they can hardly be expected to hearken; the market law of "supply and demand" is inapplicable to men who have necessities, responsibilities, and human ties. What is required is a sympathetic consideration from those who are called upon to rule over them.

How to determine the relative condition of employer and employé is one of the most perplexing problems ever contemplated by the human mind, and we will not venture beyond the region of kindly recommendation in any remarks we have to make. The telegraphic enterprise, like many other useful projects, may have been hitherto overwrought., *i.e.*, there may be more companies in England than are absolutely useful, and the business of the country divided amongst them may not prove very advantageous to either; but on this point we hesitate to express an opinion, seeing that the mass of the people have not yet recognised the immense utility of the system. It is evident that, with a limited amount of business, justice is not done to all parties engaged in telegraphic pursuits. Shareholders, solicitous for dividends, exert an influence upon directors and managers, who are obliged to appear inexorable whenever appeals are made to them for increased salaries, and thus those whose requirements are greatest are compelled to suffer.

A remedy for this condition of things is very necessary. We do not desire to unduly exalt the claims of the clerk, nor to ignore the just expectations of shareholders. We submit that a more speculative business would prove advantageous to all the companies, and recommend that special éfforts be made to secure the support of the public for the telegraph system. Existing lines might be made more productive, without any appreciable increase of working expenditure, and the profits so derived would admit of a better remuneration of the staff. What would the postal service of this country be were its advantages confined to the merchant and the manufacturing classes? The answer to this query is to be found in the fact, that instead of being a source of immense revenue to the Government, it would realise a comparatively trifling income, as telegraph companies are doing at present. Hence we are convinced that were vigorous efforts made to popularise telegraphy, resources would be placed at the disposal of directors and managers, who would not only be able to declare larger dividends, but to augment the salaries of their underpaid officers.

SUBMARINE CABLES.

III.

Mr. Latimer Clark submitted a cable for experiment of the following description:—An insulated copper wire or core served with steel wires, having a slight spiral direction, and covered with tape and a composition of shellac and marine glue. A cable of this description was weighted to 1,787 lbs.; the extension before removing the weight was = ·468 per cent., the permanent elongation = ·364 per cent., and the return, or contractile force = ·104 per cent. The Liverpool and Isle of Man cable is constructed upon the above principle, with the exception that iron is substituted for steel wires. Upon some portions of the cable being recently raised for repair, in consequence of its severance by a ship's anchor, the iron sheathing protected by the compound was found to be in a perfect state of preservation. The Wexford and St. David's Head, the Zandvoort, and the Persian Gulf cables are similarly protected against corrosion by coatings of mineral pitch, silica, and Stockholm tar, in the proportions of 34, 56, and 10 parts respectively. The last of the three cables, after the iron wires were laid on, had two coatings of the compound and two servings of tarred hemp yarn laid alternately, the first coating of the compound being next to the wires, then a serving of yarn, then compound again, and lastly yarn.

Messrs. Siemens, Halske, & Co. submitted a specimen of cable of novel construction—viz., a gutta-percha core covered spirally with fifty-six strands of hemp, and lapped with copper. The cable was weighted to 2,256 lbs.; the extension before the removal of the weight was = 1·75 per cent., the permanent extension after removing the weight = 1·15 per cent., the return, or contractile force = ·60. It had a specific gravity in water of 1·5, and possessed great tensile strength. The Oran and Carthagena cable, which has already been described in this journal, was constructed upon the same principle as the above, but much improved with regard to increased strength.

Several specimens of the proposed deep-sea portion of the then intended Gibraltar cable were furnished by Messrs. Glass, Elliot, & Co. The core consisted of a strand of seven copper wires, covered with three coats of gutta-percha and Chatterton's compound, weighing 800 lbs. per mile. The core was covered with twelve strands of steel wire and hemp, each strand consisting of one wire with six yarns of tarred hemp. This cable was weighted to 3,596 lbs.; the extension before removing the weight was = 1·927 per cent., the permanent extension after removing the weight = 1·197 per cent., and the return, or contractile force = ·73; specific gravity

in water, 1·9; external diameter, $\frac{11}{16}$ths of an inch. One of the specimens, similar to the above in every respect, with the exception of the steel wire being gauge 14 instead of 17, was not broken with a weight of 13·043 lbs. = 5,683 fathoms in length of its weight in water. A third specimen, having the same number of iron wires as the above, broke with a weight of 11,311 lbs. In testing this cable when it had a weight of about 10,000 lbs. attached to its lower end, the splicing at the top of the triangle gave way, and the consequent contraction of the iron wires acting upon the permanently-elongated core caused it to force itself through the strands of iron wire. Numerous experiments were made as to the liability of the various ropes we have enumerated to form themselves into kinks in the operation of uncoiling. We found it difficult to effect kinks in such cables as those of Allan, De Bergue, Clark, Wells & Hall, and Sinnocks, while in the other cables we found it as difficult to prevent the same taking place, and which could not be removed by tension, the core being forced between the iron wires, and the cable generally breaking at the kink. The untwisting of the ropes when subjected to tension was also observed—the cable being suspended from a triangle, its upper end being fixed and the lower end, to which the weight was suspended, being allowed to revolve. The number of revolutions with a weight of 1,787 lbs. on the Gibraltar cable was 1¾; Godefroy, 0; Silver & Co., 0; Wells & Hall, 0; Siemens, with 2,258 lbs., 1½; Allan, with 1,787 lbs., 0; Sinnocks, 1½; De Bergue, 0; Clark, 0.

THE MAGNETIC RHEOMETER.

THE method of measuring inductive charges and discharges by the momentary deflections of the needle of a galvanometer, requires the employment of batteries of considerable electro-motive force, or wires of great length, in order that the charge may be accumulated, or galvanometers of extreme multiplying power. For this purpose Professor Wheatstone recommends the employment of Mariani's Rheo-electrometer, or Magnetic Rheometer. The instrument is thus constructed:—Five yards of insulated copper wire, 1-120th of an inch in diameter, coiled round a cylindrical bar of soft iron, three inches in length and one-eighth in diameter; this bar is fixed horizontally, over a graduated circle, at a right angle to the line joining its zero points; at the centre of the bar there is an aperture, to allow the free passage of a silk fibre, from which is suspended an extremely delicate magnetic needle, weighing less than half a grain; at the top of the glass cage the upper end of the fibre is attached to a pin, which, by means of an adjusting screw, may be raised or depressed without causing it to rotate, in order to regulate the distance from the needle to the electro-magnetic bar. The ends of the coil of wire are connected to binding screws, placed outside the frame, and the graduated circle with the bar is moveable by means of a lever placed beneath the frame, in order that the zero points may be accurately brought to the magnetic meridian, without moving the instrument bodily. Four small pins are fixed on the circle, in the vicinity of the bar, in order to prevent the contact of the needle with the bar, which it would be otherwise sometimes difficult to disengage from each other.

The mode of using the instrument is as follows:—The zero line of the scale is brought, by means of the lever, into the magnetic meridian; if then the bar is entirely deprived of magnetism, the needle will place itself in that direction. On a discharge being made through the coils, the bar becomes magnetic, in proportion to the amount of the discharge; the two poles of the needle are attracted towards the two ends of the electro-magnet, causing an instantaneous deflection, and, subsequently, a permanent deviation, owing to the residual magnetism to a less amount. To prepare the instrument for a fresh experiment, the bar must be deprived of its magnetism, which is easily effected in the following manner:—One of the poles of a very weak single cell of a voltaic battery is to be attached to one of the binding screws of the instrument, while the other pole is to be brought into successive momentary contacts with the other binding screw, the current being in the opposite direction to that which produced the magnetism of the bar; each contact causes the approach of the needle towards zero, and when it has arrived at that point the magnetism of the bar is completely destroyed, but should the zero be overpassed, the same operation must be repeated, after inverting the current.

The following experiments were made with this instrument:—A Leyden jar, having 380 square inches of tinfoil surface, was charged by a Daniell's battery of 512 elements. On discharging the jar, the Rheo-electrometer showed ten degrees instantaneous, and four degrees permanent deflection. One hundred yards of copper wire, coated with gutta-percha, and immersed in water, were charged by a battery of sixty elements; when the discharge was made through the Rheo-electrometer, a deflection of several degrees was shown. In this case the discharge current could not be detected, except upon a suspension galvanometer of 30,500 coils.

RAILWAY TRAIN SIGNALLING.

UPON the first introduction of the Electric Telegraph as an instantaneous means of communication, it was fully expected that it would be speedily adopted for the above purpose, and that it would be of great advantage to the railways then extending themselves over Great Britain; but, as is usually the case with great inventions, many years elapsed before the invention was practically applied for the purpose of Railway Signalling, notwithstanding the vigorous and indefatigable efforts of the patentees to prevail upon engineers to recommend it for their lines. We have now before us a Blue Book, containing the Report of a *Select Committee* appointed to consider "whether it is desirable, for the public safety, to vest a discretionary power of issuing regulations, for the prevention of accidents upon railways, in the Board of Trade, &c.;" also the Minutes of Evidence taken before the Committee, occupying, altogether, no less than 210 folio pages. The volume contains a vast amount of information respecting the system of signals then employed, and also suggestions for improved methods of signalling, but no one ventured to suggest the application of electricity for the purpose; indeed nothing could be more discouraging than the brief allusion made to the electric telegraph, by the then Inspector General of Railways. We quote the questions, and the answers given:—

"Sir JAMES GRAHAM.—At this moment there is on the Great Western an electrical telegraph, is there not, from the point of starting to the first station out of London? Sir F. SMITH—I know that there was; I am not sure whether there still is.

"That telegraph, it is stated, is of use to prevent trains approaching the station at moments of danger?—It might be used in that way; I am not aware whether it ever was so used.

"Do you suppose that telegraph communication, being established on that line, to be of an experimental nature or not?—I should think it utterly impossible for the Government to force any company to adopt a regulation of that kind.

"If it was a practice on that line, and is conducive to the public safety, why should you say it may not be enforced?—Because I should say the public safety might be secured at a much less expense.

"But still the Board of Trade might say, 'We have the experience on the Great Western Railway, of this telegraph being conducive to public safety;' would it not be in their power, as the clause is now drawn, to prescribe that regulation, relying on the practice, and not regarding it as an experiment?—I think it might tend to cramp the commerce of the country, now carried on very much by railways, and that it would be too expensive an expedient to compel the recourse to it.

"That is a question of policy; but, under the clause as it now stands, would not the Board of Trade have a right to interfere?—I think they would have a right to interfere; but they must have their proceedings taken notice of by Parliament, and I do not see how any Government could support such a proceeding.

"You think a telegraph communication might be ordered on any railway?—We are now looking at the question of power, not its application; and as the clause stands, perhaps the President of the Board of Trade might have power to issue such a regulation, but one can hardly conceive the possibility of anything so absurd as his exercising it."

The following engineers were examined as to the system of signalling employed, all of whom ignored even the existence of the electric telegraph:—Mr. Loch, C.E.; Mr. I. K. Brunel, C.E.; Mr. G. Stephenson, C.E.; Mr. E. Bury, C.E.; besides a number of managers and secretaries. The appendix also contains resolutions respecting signalling, &c., passed at a meeting held at Birmingham on the 19th January, 1841, at which were present

deputations from various companies, representing a capital of fifty millions sterling. The following is a copy of the first and principal resolution:—"That in consequence of the public anxiety, occasioned by the accidents which have taken place on various railways, the companies here represented, in order to profit by the combined experience of the principal lines, have deemed it expedient that a general conference should be held, for the purpose of taking into consideration the causes and circumstances of such accidents, and the means that may be available of more effectually guarding against their occurrence for the future."

Every possible means were suggested for "guarding against the occurrence of accidents," except that of the electric telegraph, although its applicability for the purpose was, and had been well known to several of the engineers and managers present at that meeting, but the invention, not having had its origin in our favourite Westminster, "found no favour in our eyes." We shall, on a future occasion, explain how telegraphy became a "branch of our profession."—C. E.

THE INTERNATIONAL EXHIBITION, 1862.

(Continued from page 89.)

2. *Sending Keys, or Instruments with which the Signals in the above Codes are sent by hand.*

Morse signals are usually transmitted by a simple rocking lever, worked up and down by hand between two stops. The lever is in connection with the line, and one stop with one pole of the battery. The other stop used to be a blank, but is now, with the best effect, generally connected with the earth, and serves to discharge the line. Messrs. Siemens, Halske, & Co., for work through submarine cables, connect it with the opposite pole of a second battery.

The British and Irish Magnetic Telegraph Company, M. (United Kingdom, 2,864), exhibit an excellent finger key, or, rather, pair of keys, by which the reverse voltaic currents, required for the Steinheil, or similar codes, can be sent with great rapidity and little fatigue to the operator. Two flat spring keys are placed side by side, one for the positive and the other for the negative signals; in their position of rest, the current sent from the far station can pass through the near receiving instrument to earth, but when either of the keys is depressed the near receiver is first cut out of circuit, and the positive or negative end of the battery joined to the line, and the other pole is put to earth. This key is used either in connection with the needle instrument, or with the acoustic telegraph, to be presently described.

Siemens, Halske, & Co., M. (United Kingdom, 2,959), exhibit a magneto-induction key, by which signals can be sent through circuits of great length without the use of any battery. The handle of the key is worked in exactly the same manner as the common Morse rocking lever. The adoption of their polarized receiver, which will presently be described, has allowed these instruments to be used for the transmission of common Morse signals, and may lead to their extensive use.

The arrangement of the magnet and coils, by which the reverse currents are induced, is extremely simple and good. A series of horseshoe magnets are placed side by side, separated by spaces of about the same thickness as the magnet plates. A soft iron bar with an H cross section is placed between the poles of the magnets, and is supported on a longitudinal axis allowing a partial rotation to be given to it by a handle. The wire of the induction coil is wound longitudinally round the bar from end to end parallel to its axis, and consequently crossing the planes of the magnets at right angles. The coil is protected outside by a brass plate, and the iron bar, coils, and brass plates then form a long prism of rectangular section, supported at the ends by two bearings. This rectangle very nearly fills up the space between the poles of the magnets, so that the handle, which is on the axis, can only turn the bar through a very small angle. When the handle is up, two diagonally opposed corners of the rectangle are in contact with the two poles of the permanent magnets, and these magnetise the bar transversely in a given sense. When the handle is depressed, the two remaining corners on the other diagonal are brought against the poles, and the bar transversely magnetised in the opposite sense. In other words, as the handle is worked up and down, the opposite poles of the permanent magnet are alternately brought in contact with the same end or head of the H iron, although not with the same corners. The change of magnetism in the iron induces the required reverse currents in the coil, one end of which is connected with the line and the other with earth. The handle is worked in exactly the same manner as the usual voltaic Morse lever, but requires, of course, more power to work it, since the current obtained is really the equivalent of the power exerted.

The handle moves through a very small arc—a great advantage to the operator; and the arrangement generally has some other advantages which will be pointed out when Messrs. Siemens' step-by-step dial instrument, worked by similar coils, is described. A key of this kind worked a direct acting ink-writer with a resistance in circuit equal to 468 miles of No. 8 iron wire.

W. T. Henley, H. M. (United Kingdom, 2,908), also exhibits a magneto-key, in which he uses the same arrangement of permanent magnet, soft iron armatures, and horseshoe with coils, as in his step-by-step magneto-transmitter, which will be presently described. He requires three soft iron armature pieces, one opposite the upper soft iron pole, and two opposite the lower pole. The reciprocating motion of the key allows these three armature pieces to produce the same series of alternations of polarity in the soft iron horseshoe as are produced by the continuous motion of the rings in the step-by-step instrument. The key exhibited worked a direct acting ink-writer, exhibited by Messrs. Siemens, with a resistance equal to that of 468 miles of No. 8 iron wire in circuit. These two magneto-keys can obviously be used in connection with needle-receiving instruments, to which, indeed, magneto-keys were first applied.

The Telegraphen Werkstätte, of Berne (Switzerland, 151), exhibit an ingenious key for the transmission of Morse signals by the secondary currents of an induction coil. One current—say the negative—is used to produce the marks, and the other, or the positive, the intervals. It is intended to be used in connection with a Morse receiver or relay, having what may be called an unstable armature, which will remain in either position to which it is moved by a positive or negative current, even after the interruption of that current. A receiver of this kind can only be worked by alternate positive and negative currents, and the armature, in moving from one stop to the other, necessarily passes through a position in which, when no current is passing, it would be in unstable equilibrium.

The positive and negative secondary currents sent by this key are of equal strength, and both produced by the interruption of the primary current. A single battery only is used; this battery is never in a short circuit, and is closed through the primary coil for a very short time during each signal. These desirable results are obtained by very simple means.

The key consists of a rocking lever worked like that of the usual Morse key, with two contact pieces, which will be called A and B, at the two ends of the lever, both on its upper side. The lever is connected by its axis with one pole of a battery. A second lever, immediately over the first, rocks on an axis parallel to that of the first, and has two insulated contact pieces, A′ and B′, on its lower side, facing A and B of the first lever. This second lever is made of a magnet or magnets, and two armatures of soft iron are fixed immediately over the poles, which are themselves immediately over the two contacts, A and B. These armatures are used, as will be seen, to attract the second lever into one of two extreme positions, and to hold it there until removed by the first lever. The two insulated contact pieces, A′, B′, are both connected with the other pole of the battery by means of two distinct insulated wires wound in opposite directions round the core of the induction coil, and forming two distinct primary coils. One end of the secondary coil is connected with the line, and the other, through the home relay, with the earth.

By this arrangement a contact between A A′ sends, say, a current from right to left round the induction coil, and a contact between B B′ sends a current from left to right round the coil from the same battery, but through a separate wire. The position of these several parts is so adjusted, that when the first lever is at rest neither of the contacts, A A′ or B B′, is completed; but one end, say B′, of the second or magnet lever rests against its armature. When the first or hand lever is depressed it first makes contact between A A′ (at the opposite end of the magnet bar). This closes one of the primary circuits, sending a current from right to left round the induction coil, and so induces, say a positive secondary current in the line. It will presently be seen that this current, being in the same direction as that which must have preceded it, does not move the armature of the receiving relay or instrument; in fact, it produces no visible effect at the receiving end of the line. As the downward motion of the hand lever continues it next removes the end, B′, of the

magnet lever, and when it reaches its limiting stop, it has brought the opposite end, A′, so near to the other armature, that it springs up, breaking the contact, A A′, made shortly before. This interruption induces a current in the secondary coil opposed to that last sent, or transmits, say, a negative current through the line, and so moves the armature of the receiving instrument from the position in which it had been left by the last positive current, and produces a mark or sign. When the hand lever is allowed to rise it shortly completes the contact, B B′, and sends a current from left to right round its primary coil; the current induced in the secondary coil is in the same direction as that last sent, resulting from the interruption of a current flowing from right to left; it therefore produces no visible effect on the receiving instrument. As the rise of the hand lever continues, it removes the end, A′, of the magnet lever from its armature, and when it reaches its limiting stop, it has brought the end, B′, so near to its armature, that it springs up to it, breaks the primary circuit, and so induces a positive secondary current, which moves back the armature of the receiving instrument, and produces the space or interval following the mark.

Thus, when the first lever is worked by hand, four successive currents are induced in the line; the first and fourth are positive, the second and third negative; the second and fourth are currents by interruption, and they alone work the receiving instrument, the armature of which is unmoved by the currents of the same name which follow. It will be observed that the two primary circuits are only completed for a very short time during the motion of the hand lever, and that both in the upper and lower position of that lever the two ends of the battery are insulated from one another.

The sending clerk sends through his own receiving instrument, which is a disadvantage; but, on the other hand, he can in consequence be interrupted at any moment by the clerk at the far end.

This key is ingenious, and would, no doubt, fulfil its objects in practice; it is much superior to those induction keys in which the alternate currents are unequal, but it does not clearly appear what advantage is expected over the usual voltaic or magneto-electric signals.

The British and Irish Magnetic Telegraph Company, M. (United Kingdom, 2,864), exhibit the only instrument designed to remedy in any way the retardation or interference produced by induction in long submarine cables on the signals transmitted through them. This instrument is a compensation sending key, invented by Sir Charles Bright, and is described by the exhibitors in the following words:—

"It has been found necessary in working long circuits to provide for the irregularities of charge produced by different currents. This was pointed out by Professor Thomson in 1856, and others have, as well as himself, made various contrivances for the purpose. The key now shown is one of a simple form, invented by Sir Charles Bright, for circuits of ordinary length, adapted to the use of the common Morse alphabet by the most ordinary operator. Not intended as affording *perfect* compensation for *very* long circuits, but as an every-day instrument, cheap and simple in regulation, and fit to be put in the hands of any telegraph clerk. On pressing down the key, a lever begins to rise, being governed in its rate of motion by gearing into a small train of wheels controlled by a fan, or any other regulator capable of convenient regulation. If a *stroke* is sent, the lever rises as far as a stop, against which it rests until the signal ceases by the key rising. When it touches, the step part of the battery is cut off, or the whole power may be cut off if desired, thus adding to the pause as well as cutting off part of the stroke sent *into* a line, which is equalised at the distant end by the effects of induction."

This key would accomplish the limited object aimed at by the inventor.

3. *Galvanic Batteries.*

Batteries are, perhaps, worse represented in the Exhibition than any other adjunct of telegraphy. In one form or another Daniell's battery is now chiefly used by the large telegraph companies, although for many other purposes Smee's battery is retained. This latter single fluid battery is, no doubt, a useful form wherever the circuit is seldom closed, and only for short periods at a time; but the simplest experiments show that single fluid batteries will not produce a constant current in a closed circuit for five minutes together, and are, therefore, entirely unsuited for the delicate and accurately adjusted receiving instruments now used.

J. A. Deleuil, Paris, M. (France, 1,421), exhibits a battery known as the "pile Marie Davy," in which sulphate of mercury and carbon electrodes are substituted for the sulphate of copper and copper electrodes of the Daniell's battery. This new form is clean and constant, but it is weaker than the Daniell's cell; it has considerable inherent resistance, and is expensive in the first instance. It is portable, and has been used to some extent in France.

Reid Brothers (United Kingdom, 2,949) exhibit a compact form of Daniell's battery. A glass trough is subdivided into cells by five partitions; this cellular trough is formed of one solid piece of glass. Each cell is again subdivided by a porous plate, cemented at each side and at the bottom between two cheeks. The zinc and copper plates connected in pairs stand astride the glass partitions, and the subdivisions are alternately filled with sulphate of copper and acidulated water. This battery is strong and portable, but the porous plates when worn out can only be removed and replaced with difficulty.

J. Gressler & Co., Berlin, H. M. (Prussia, 1,402), exhibit various sizes and forms of Bunsen's double fluid battery, with strong and simple copper connections. The prices quoted are moderate. The largest size shown had carbon cylinders twelve inches high.

E. Tyer (United Kingdom, 2,977) exhibits a simple and convenient form of Smee's battery, which seems well suited for some purposes. The zinc plates can be readily removed, cleaned, and replaced; they lie in a saucer of mercury, which fulfils the double purpose of maintaining the zinc constantly amalgamated, and of making contact between the zinc and the copper strip which connects the zinc with a platinized silver plate in the next cell. This copper strip is insulated by gutta-percha, except where covered by the mercury.

Very little local action can take place, owing to the thorough and constant amalgamation of the zinc, and, therefore, if the circuit be only occasionally closed for short periods, as when used for train signals or house bells, this battery will remain very constant; but it of course possesses all the unavoidable defects of single fluid batteries. Several thousands of these batteries are at work. The platinized silver plates are found to decay somewhat rapidly in practice.

C. V. Walker, H. M. (United Kingdom, 2,983), exhibits platinized graphite plates to be used instead of the simple graphite plates in Mr. Walker's modification of Smee's battery, which was highly commended in 1851. Mr. Walker states that by platinizing the graphite plates the liberation of the hydrogen gas from their surface is much facilitated, and polarization—one great defect of single fluid batteries—thereby much diminished; the cost of the process is about one halfpenny per plate of the usual size of 7 in. × 3 in. The platinized plates are also said to keep much cleaner than the simple graphite plates.

J. Young, Dalkeith, H. M. (United Kingdom, 2,997), exhibits some very dense and well-made carbon elements of various forms, for batteries, and for the electrodes of electric lamps.

A. Rodler, Nuremberg (Bavaria, 1865), exhibits some well-made carbon elements for galvanic batteries.

(To be continued.)

UNIVERSAL PRIVATE TELEGRAPH COMPANY.

THE Annual General Meeting of the Shareholders of this Company was held at the Society's Offices, 448, Strand, E.C., on Wednesday last, Mr. Alderman Salomons, M.P., in the chair.

The Secretary having read the advertisement calling the meeting, the Chairman next proceeded to affix the Seal of the Company to the List of Shareholders; after which he called upon the Secretary to read the Report, which stated that a year ago the Directors met the Shareholders with a great degree of confidence in the ultimate success of their operations, and of their convictions that capital alone was essential to the development of a remunerative business.

The accounts then circulated had been made up to August 31st, 1862, at which date they exhibited a favourable result, except as regarded the capital, which was clearly insufficient to develope the works commenced. The Directors found it necessary to obtain certain modifications in their agreement with Professor Wheatstone, which he cordially acceded to, and which will tend no less to his benefit than to that of the Shareholders at large. These arrangements having been completed, the Directors proceeded to distribute amongst their friends the remainder of the share capital, for all of which subscriptions were tendered (principally in Glasgow and Manchester), but in deference to the wishes of the Engineer, who was under the impression that Newcastle and Liverpool would desire to take a pecuniary interest in the Company, 827 shares were reserved for that purpose. After encountering considerable obstacles, the Directors have at length secured the consents requisite to the introduction of the Company's wires into Liver-

pool, and as soon as a sufficient rental can be engaged, the works will be proceeded with.

At Newcastle the system has been developed in a very satisfactory manner, and the same may be said with regard to Glasgow, and Scotland generally. At Manchester some progress has been made, but not to that extent which might have been attained had trade flowed in its usual channels. At Belfast the Company's system has recently been introduced with every prospect of remunerative business.

The accounts, as made up to the 31st September last, are presented herewith: the capital account showing a total expenditure of 61,764*l.* 0*s.* 5*d.*; in the revenue account, the balance standing to the credit in the published statement of 31st August, 1862, is brought forward, and the net revenue is now enhanced to 3,812*l.* 7*s.* 7*d.*, out of which the Directors recommend a dividend upon the shares for the past year after the rate of 5 per cent. per annum, which will absorb 1,784*l.* 6*s.* 2*d.*, leaving a reserve of 2,028*l.* 1*s.* 5*d.* The growing importance of the Glasgow district has been felt to require special recognition, and the Board feel so convinced of the value of that branch of the Company's system, that the four Directors who retire by ballot at this period do not offer themselves for re-election, and it is proposed that three of the seats thus rendered vacant shall be filled by gentlemen chosen by the Glasgow Committee. In pursuance of this arrangement, Messrs. John Cameron, James Reid Stewart, and Walter Mackenzie have been selected, and are recommended for election.

Domestic affliction having occasioned the temporary retirement from the Board of Mr. Sam. Mendel, the Directors appointed Mr. Jonathan Mellor in his place. Mr. John Wood also retired in favour of Mr. J. G. T. Child, whose services, it was considered, would make a change for the advantage of the Company, and who was accordingly appointed to fill that vacancy.

23rd February, 1864.

The Chairman then said that he was glad to see so many present on that occasion. There had been no meeting of the Shareholders since that time last year, and though at that time their Company looked in a good condition on paper, they found that capital was wanted in order to obtain success, and he was glad to say that now they had capital enough for all reasonable purposes. They had an excellent working committee, who looked well after the interests of the Company. They had introduced their system into Liverpool, and it might have been supposed that there they would not have met with any difficulties, but impediments were met with in everything, however useful it might be, and they had found in this case that they were not free from all the incidents connected with the introduction of a new company. For some time they laboured under the disadvantage arising from the want of capital, but that was not the case now. Considerable exertions had been made by the members of the Glasgow Committee, for which district a number of shares had been reserved, all the rest having been disposed of. The directors had well considered what was right to be done for the prosperity of the company, and some had run considerable risk to bring the company to be a success; for it was found that, without having fresh capital subscribed for, they could not make it productive. He (the Chairman) was glad to inform them that the affairs of the company were now in a prosperous condition, and that the directors had agreed to recommend a dividend on the shares at the rate of 5 per cent. per annum, and that, after deducting 500*l.* for the maintenance fund, they would have a balance of 1,600*l.* due for rentals. Their system was working well in Glasgow, as well as in other parts of Scotland, and he believed that the results would be most satisfactory. There had been some alteration made in the board of directors, which would render it more efficient; the four directors who retire by ballot on the present occasion, not offering themselves for re-election, three to be proposed in their stead, representing the Glasgow interest. That being the present position, and the future prospects of the company, he had now only to move the adoption of the report and the statement of accounts, with the payment of a dividend, at the rate of 5 per cent. per annum, which was carried unanimously.

The Chairman next proposed that Mr. John Cameron, Mr. James Reid Stewart, Mr. Walter Mackenzie, and Mr. J. G. T. Child be directors, in the place of those gentlemen who retired by ballot on the present occasion. It would be found by that proposition, that the directors had been desirous of having Glasgow represented on that board, and they asked the sanction of the shareholders thereto; for it was considered that Liverpool and Glasgow should be represented at the board, according to the capital subscribed for by those towns. There was still a large field in London which might be worked up, and yield an excellent return to the company. Mr. Sam. Mendel, to whom the company owed a great deal, from the capital and influence he had brought to bear on behalf of the company, resigned his seat at the board, entirely on account of indisposition, finding that his health precluded him from attending to the duties as he wished, and he hoped that those gentlemen who would come on the board would be found a source of strength and influence for the good of the company. The motion having been put, was carried unanimously.

Messrs. Alison & Waddell were next re-elected auditors for the year ensuing.

Mr. J. Mellor then proposed "that the thanks of the shareholders be given to the chairman, Mr. Alderman Salomons, M.P., for presiding on the occasion, and for the interest he had taken in the general welfare of the company.

Mr. S. Gregson, M.P., seconded the proposition, remarking that it was a source of astonishment to him that their Chairman was able, with his numerous engagements, to devote so much valuable time to the interests of the company; he therefore felt that he deserved their best thanks.

The motion having been put, was carried with acclamation. The Chairman in acknowledging the compliment took occasion to say, that he would repeat what he said last year, that he had found the greatest assistance from their excellent Secretary, Mr. Hertslet, and he did not know any company where the directors had a more zealous and efficient one. He could not say all in his presence which he deserved, but he felt at liberty to say just so much; for a great deal of the prosperity of the company in London was due to his gentlemanly conduct.

The business of the meeting then terminated.

BRITISH AND IRISH MAGNETIC TELEGRAPH COMPANY (LIMITED).

Mr. Langton (in the absence of Mr. J. C. Ewart, M.P.) presided at the annual meeting of the shareholders of this company, which was held in the Clarendon Rooms, Liverpool, on Wednesday, the 24th instant.

The report and accounts having been taken as read, the Chairman congratulated the shareholders upon the success which had attended their operations during the past year. They had suffered increased competition, and had to work in certain parts of the kingdom at reduced rates. In addition to this, both of their cables between England and Ireland became partially useless in the autumn, and so stormy was the weather at that time, that the replacement of the cables cost nearly 6,000*l.*; the operations—which under favourable circumstances would only have occupied a week—having extended over three months. Still, in spite of this, they were not only able to place the whole of this charge upon the year's revenue, but to declare a dividend of 5 per cent. upon the half-year, making the average dividend on the year 4¾ per cent. against 4½ per cent. on the previous year.

A variety of resolutions of a formal character were passed unanimously, and the retiring directors and auditors were all re-elected.

The Chairman also alluded in feeling terms to the serious illness of the secretary, Mr. E. B. Bright, and expressed a hope that the company would soon again have the benefit of his valuable services.

The proceedings terminated with an unusually hearty vote of thanks to the chairman.

COLONIAL TELEGRAPHY.

THE ELECTRIC TELEGRAPH AT THE CAPE.

By far the most important event of the month, regarded with a view to its ultimate effect upon the development of the resources of the colony and its political institutions, has been the public opening of the electric telegraph between Cape Town and Graham's Town. The formal opening took place on Friday, the 8th proximo, when, by invitation from Mr. Wollaston, the general superintendent of the company, his Excellency the Governor, Lady Wodehouse, and suite, the members of the Executive, the Judges, the heads of departments, and a numerous company of ladies and gentlemen assembled in the large hall of the Commercial Exchange, which had been temporarily connected with the telegraph. The instrument was placed upon a table in the centre of the room, around which the company gathered to listen to the explanations, and witness the illustrations of its action given by Mr. Wollaston. The system of telegraphy employed is Morse's improved by the contractors, Messrs. Siemens, Halske, & Company. Congratulatory messages on the completion of the line were exchanged between his Excellency the Governor and the Municipalities of Mossel Bay, Port Elizabeth, and Graham's Town, and other persons. On the following Monday the line was opened for the use of the public, and has since been fully employed. The amount of business far exceeds expectation. The scale of charges adopted is very moderate. The line is most substantially constructed, and messages between Cape Town and Graham's Town are transmitted the entire distance of six hundred miles without the necessity of repetition. Sir Thomas Maclear, the Astronomer Royal, bears high testimony to the character of the line, in the following letter to the Editor of the *Cape Town Argus*:—

Sir,—It is suspected that the Graham's Town authorities missed the complimentary message from his Excellency the Governor in consequence of not allowing for the difference in longitude between Graham's Town and Cape Town.

The meridian of Graham's Town is thirty-one minutes fifty-nine seconds, or, in round numbers, thirty-two minutes east of the Royal Observatory; therefore, the hands of a clock adjusted to Graham's Town local time are thirty-two minutes farther advanced on its dial at any given instant than the hands of the Observatory dial. For example, one o'clock Observatory time is coincident with thirty-two minutes past one Graham's Town time.

I was not near the message instrument while the operations were going on, but I am told that the messages were forwarded to the localities in the order of increasing distance—the method adopted at the great telegraph exhibition at Manchester some three years ago.

Suppose his Excellency's message to have been transmitted at half-past one o'clock, the corresponding Graham's Town time would be two minutes after two o'clock—late enough for the exercise of patience on an occasion so interesting, if the longitude was overlooked, or for suspecting a mishap to the wire.

The following longitudes of stations on the line are derived, save one, from Captain Bailey's geodetic operation:—

	East of the Royal Observatory.	
Mossel Bay	14 minutes	31 seconds.
George	15 „	57 „
Uitenhage	27 „	41 „
Port Elizabeth	28 „	35 „
Graham's Town	32 „	0 „

For any given instant the local time at each of these stations appears to be *later* than the time at the Observatory by the numbers here recorded.

For example, suppose the instant of the one o'clock time-ball signal given from the Lion's Rump, to be transmitted along the line, the clock at Mossel Bay, if correct, would indicate one hour fourteen minutes thirty-one seconds, and so on for the others. In England little attention is paid to local time. Greenwich time is signalled throughout the kingdom, by which arithmetic and uncertainty are got rid of.

The longitude of Swellendam has not yet been investigated.

I shall now offer a few remarks relative to the character of the line of telegraph which has been established—which I would have stated at the meeting on Friday, if circumstances had afforded a fitting opportunity—premising that my intimacy with Mr. Wollaston is sufficiently slender to relieve me from bias, were I capable of indulging it on a question of public service, which doubtless he will understand.

When the contract was being made with Mr. Pickering it was urged, on the part of Government, that the line wire should be number 6, instead of number 8, because its transmitting power, irrespective of the advantage of its strength, would be in the ratio of 1·4 to 1—viz., nearly one half greater than number 8. This was refused on the part of the contractor, and instead "equal to the best telegraphs in England" was introduced. Mr. Wollaston left for England the day after the contract was signed.

Little was heard of the telegraph contract for many months, and that little was not over encouraging. In the meantime, I rendered all the advice and assistance at my command in support of the badly established segment between Port Elizabeth and Graham's Town, and to its still more rickety cousin between Cape Town and Simon's Town.

At length a company was got up in London to carry out the contract. Mr. Wollaston returned to the Cape, accompanied, to my astonishment, by Mr. Hoeltzer, of the house of Siemens & Co., one of, if not the most celebrated scientific telegraph engineering firms of the day. No. 6 wire was to be adopted, and to be carried by their iron-clad insulators.

To whom the credit is due of engaging that firm I know not, nor is it my business to inquire. I only know that it was sound policy to do so, because Siemens & Co. have a character to support, and would prefer incurring a loss to damaging it by flimsy work.

Experiment has proved the wisdom of the policy. The line is established, and with fifteen cells only of Daniell's constant battery, a through message has been sent from Cape Town to Graham's Town.

(By a through message is meant with the sections of the line joined up, without an intermediate relay.)

Mr. Hoeltzer is my authority for this statement. To work a registering instrument at the distance of 600 miles with only fifteen cells is a very strong proof of a well-insulated wire, notwithstanding the advantage of a dry warm atmosphere. To deflect a delicately-suspended needle is another matter.

With respect to the quality of the supporting poles beyond the immediate neighbourhood of Cape Town I know nothing; those I have seen are very good. It is a pity that iron poles were not available; they are far cheaper than wood in the long run.

Upon the whole, in my humble opinion, the colony has made a good bargain.—I am, &c., THOMAS MACLEAR.

Royal Observatory, Jan. 11, 1864.

TELEGRAPHY IN NORTH BRITISH AMERICA.—The first step towards opening up that splendid country is obviously the construction of a line of telegraph from Fort Garry westward—an enterprise rendered the more certain of success from the fact that a line of telegraph is steadily advancing from Europe to the East to meet it, and which, in a but comparatively short time, will make it possible to telegraph from London to Fort Garry, by way of Siberia and British Columbia. The connection between Fort Garry and Montreal is essentially a Canadian question, and can be dealt with in no other way—the Hudson's Bay Company having no right to the land through which such connection must be made. This matter was brought under the notice of Parliament last session by papers laid before the House by the Government. From them it appeared that negotiations had taken place with reference to an annual subsidy from Canada, in conjunction with British Columbia and Vancouver's Island, to secure a through line of telegraph and a waggon road between the two oceans. The two last named colonies have, it is stated, agreed to their share of the subsidies, but at present Canada has not. Canada can, therefore, it would seem, secure a telegraphic communication with Fort Garry whenever she likes, either by an annual subsidy to a private company or by making the telegraph line herself. This must of course dispose of any fear, as has been suggested, that the proposed line of telegraph through the Hudson's Bay territory is to be made subservient to American interests. The American system of telegraph lines is now in operation nearly 50 miles north of St. Paul and some 350 miles from the British line at or near Pembina, which is only 50 miles from Fort Garry. That the Americans will carry their line of telegraph to Pembina it would be absurd to doubt, or that they will seek a connection there with any line that may be made westward from Fort Garry. And why should they not? If a telegraph is completed between Europe and Fort Garry, the practical eastern terminus of the Hudson's Bay Company's control, would it not be absolutely essential that it should be connected with the lines in the United States, and is it not desirable that connection should be made as far east as possible? A line of telegraph already exists between New York and San Francisco. It will doubtless seek to connect with any line coming from Europe by way of Behring's Straits by a junction on the Pacific coast. How much better for British interests that that such connection should be made at Fort Garry instead. A line of telegraph through the Saskatchewan valleys, with its posts every 30 or 40 miles, selected with care and judgment, and forming the nucleus of settlements, will very soon force on the question of roads and railways through the country. A waggon road, indeed, already exists from Fort Garry to the base of the Rocky Mountains—a road perfectly well defined, and which, before the American war broke out, was travelled by upwards of 300 persons in one spring. The construction of a line of railway will in time follow the telegraph. It is, perhaps, not generally known that the only practicable road from the east to the west on this continent is through British territory. The United States have reached the limit of the cultivable land in their territory; west of it lies a great rainless desert, bare of vegetation, destitute of timber, with a soil as dry as sand, and in some parts of which rain has not fallen for 22 months.

OVERLAND TELEGRAPH.—We are glad to find that steps are being taken to open negotiations with the California State Telegraph Company to extend their line to Victoria from Portland, to which point it is to be finished in a few weeks, according to our latest Oregon advices. We understand that J. J. Southgate, Esq., has replied to the letter addressed to him by Mr. Carpentier, President of the State Telegraph Company, encouraging him in his proposition, and inviting him to come to Victoria to lay his plans before the House of Assembly. We earnestly hope that his advances may be met in the most cordial manner by the House and the community at large, and that every endeavour may be used to secure so great a boon as the proposed scheme offers.

CORRESPONDENCE.

ELECTRIC AND INTERNATIONAL TELEGRAPH COMPANY.

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—I cannot but believe that many of the shareholders of the Electric and International Telegraph Company, who, like myself, were absent from the last half-yearly meeting, must, upon reading the evidently faithful account of that meeting which appeared in your journal, feel somewhat ashamed of the proceedings of those who were present upon that occasion.

I do not allude to the mere fact of their refusal to carry out the directors' proposition of granting an annuity to Mr. Fourdrinier, because that is a question on which, notwithstanding that there are plenty of precedents for such an arrangement, many persons may raise, as several of the speakers did raise, valid objections; but, sir, I do think that many, and especially the older shareholders, will feel with me, that in past years, when there was quite as much legitimate freedom of discussion at the meetings of the company as exists now, such a personal attack as that made by Mr. Reid, upon the late secretary, would never have been permitted, and I confess that I am astonished that neither the chairman or the meeting interfered to stop it. Of one thing I feel sure, that had such an attempt been made to lower the reputation of the late secretary in the estimation of those whom he has so faithfully and zealously served, when the late Mr. Ricardo filled the chair, he would either have stopped it, as being irrelevant to the question, or he would have answered it in such a manner as would, probably, have awakened in Mr. Reid what little remorse he is capable of feeling. I have been told that Mr. Reid has been heard more than once to wish for the "old chairman" back again. I presume, therefore, that in common with many others, he held a high opinion of Mr. Ricardo's judgment. Does he know, as I do, that in the estimation of that gentleman, to whom I am told all the officers of the company are deeply attached, no one member of the company's staff occupied a higher position, for zeal, industry, and integrity, than did Mr. Fourdrinier? What bearing upon the proposal of the directors had the tales of Mr. Reid, as to the origin of Mr. Fourdrinier's connection with the company, even though he had proved, as he utterly failed to do, anything of which that gentleman need be ashamed? What matter was it to the meeting of January, 1864, who first introduced that gentleman to the company fifteen years ago, provided he has filled his appointment, as he undeniably has during that long period, to the entire satisfaction of his directors, whose esteem and friendship he enjoyed to the last. As to Mr. Reid's extravagantly absurd assertions "that any stockbroker's clerk would have performed the duties of secretary for £100 per annum, and would have performed them better than Mr. Fourdrinier," they need little comment; for I think that any one, who has been brought much into contact with Mr. Reid, will agree with me, that of all persons in the world, he is about the least fitted to form a judgment of what the duties are of a secretary to an important public company, or of the manner in which they should be performed. There are, however, very few shareholders who have had the same opportunity that I have had of knowing that Mr. Fourdrinier's labours for the company did not, like those of the other officers, end with office hours, but that even his leisure hours, if they may be so called, were largely devoted to the study of matters in which the company's interests were involved, and that, in fact, the advancement and prosperity of the company was the all-absorbing subject of his time and thought. With respect to the alleged severity towards the clerks, and the "toadyism" towards the directors, I do not believe that Mr. Reid could ever have been in a position to know much, if anything, of the secretary's behaviour towards the one or the other; but this I do believe, sir, that Mr. Bidder, the only one of the directors who was man enough to stand up on behalf of their late officer, hit the right nail on the head when he stated it as his belief that Mr. Reid's unworthy attack was dictated by personal animosity.

It is not an unusual thing, sir, for a zealous officer such as Mr. Fourdrinier is admitted by every one but Mr. Reid to have been, to interfere materially with the interests and the gains of contractors. It is quite possible that Mr. Fourdrinier's predecessor, who appears to have enjoyed a so much higher position in Mr. Reid's estimation, was not so careful of the interests of the company in respect to contractors' profits, and that with the change of secretary Mr. Reid's successful career as a telegraph contractor was shortly brought to a close. If this be so, have we not a key to the violent animosity displayed by the ex-contractor towards the ex-secretary. So much, sir, for the attack and the quarter from whence it sprang; but what am I to say of the ungenerous absence of any defence (Mr. Bidder's remarks always excepted) on the part of the Board, of the gentleman upon whom the chairman had just before been passing an eulogium? Have those gentlemen lost all their spirit, that they tamely allow a few personal remarks from one of their old contractors to negative a proposition which it is but fair towards them to suppose they did not lay before the meeting until it had received their full and serious attention? Would such a thing have happened in the old times? Sir, I think not; and I feel sure that if the directors of the telegraph company wish their officers to work with that hearty goodwill and industry to which they have borne such willing testimony in the case of Mr. Fourdrinier, they must in future show a little more generosity than they have done in this instance in upholding the reputation of those officers against such an attack as that of Mr. Reid, and a little more determination and energy in insisting upon their recommendations being carried out, at all events in spirit if not to the letter, where the welfare of their staff is concerned.

ONE WHO WAS UNABLE TO ATTEND THE MEETING.

Paris, Feb. 17, 1864.

THE PNEUMATIC APPARATUS.

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—Mr. France states that Mr. Jones called on him, "towards the end of 1860, about these very relays." If this is intended to convey any impression at all it must be this, that Mr. France saw Mr. Jones relative to the construction and working out of these relays, as no other impression would be of any value to Mr. France's argument.

Mr. Jones has authorised me to state positively as to this, the first pneumatic arrangement ever made, that not alone did he receive no instructions whatever from Mr. France, but that he never saw that gentleman until long after the complete instrument had been delivered to me at the Submarine Telegraph Company's office, nor did he ever see him as to the mode of constructing or working out any of these arrangements.

Mr. Jones further informs me that he introduced himself again to Mr. France, in 1862, as the maker of Andrews' pneumatic arrangement, and that he had always understood this to be my invention.

Mr. France further says, "Why does not Mr. Guy furnish the account?—this would settle, once for all, whether any were made before my return from the Mediterranean, in February, 1860." This is a ghost raised by Mr. France for the purpose of being slain by him. Throughout this discussion it has never been stated that these arrangements were made before Mr. France's return from the Mediterranean. What was distinctly said was, that they were "mooted and proposed," and it was also expressly said that they were long in hand.

Mr. France sends a letter written him by Mr. Shaw after I left the company, in which he uses the words "your pump-relays." Mr. Shaw was stationed at Cromer—just 126 miles from the metropolis—during the whole of this period, and wrote from Cromer; he could, therefore, know positively nothing as to who invented the apparatus.

Mr. France writes, "Mr. Harwood's letter plainly says some of these apparatus (pumps, namely,) were at work when he took charge at Cromer." I refer your readers to Mr. Harwood's letter.

Mr. France occupies the extraordinary position of claiming an invention that he had nothing to do with the planning, or ordering, or working out of, and that he never saw until it reached the Submarine office a complete instrument.

Mr. France is now where he was at first, without a scrap of positive evidence connecting him with the invention, and with his mere statements, wherever necessary, confuted.

I believe that I could have closed this matter earlier, but on applying to the Submarine Company for permission to inspect the books and letters of my department during the period in question, I was informed that the keys of the iron safe, and boxes containing them, were lost, or mislaid, and as they were expected to be found, there was an objection to break open these things; I have, therefore, only been able to reply to Mr. France from memory.

I am, Sir, your obedient servant,

W. ANDREWS.

Melbourne Cottage, North Brixton,
Feb. 25, 1864.

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—Both Mr. Andrews and Mr. France are very old and good friends of mine, and it is therefore with great regret that I find my name mentioned in their correspondence on the pneumatic relay. Mr. France, I believe, connected the first pneumatic relay up at Cromer in the early part of *October*, 1860; and from this circumstance I must have drawn the inference that he was connected with the invention, as I cannot remember any direct information on the matter until after I had resigned the Submarine Company's service, when, in a conversation with Mr. Andrews on his various inventions and apparatus, I mentioned Mr. F.'s name in connection with the pump relay. Mr. Andrews at once and most emphatically declaimed against Mr. France being the inventor; and to establish his own claims most decisively, Mr. Andrews had many preliminary drawings and plans.

This conversation took place before it was proposed to adopt the pneumatic relay on the Persian Gulf lines, and *many months* before the correspondence in the "Telegraphic Journal."

I regret to find that the present clerk in charge at Cromer speaks so disparagingly of the apparatus, described in the correspondence as No. 3, as both Mr. France and myself reported very favourably of it; and I have no doubt, that but for the simplicity and less cost of the pneumatic relay, it (No. 3) would still be at work on the Submarine Company's lines.

I am, Sir, yours very obediently,

WM. H. SHAW.

Newcastle-on-Tyne, Feb. 23rd, 1864.

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—I think your readers will agree with me that Mr. France's statements require no further refutation than is contained in his own letters of the 6th and 20th instants. In the former he says, in reply to my statement that he did not see the workmen about the pneumatic relays, "When I went to Aldersgate-street I was invariably addressed direct to the workmen"—leading your readers to infer that my statement was untrue; but when, in my letter of the 13th, I proved that what I there stated was correct, he suddenly turns round and says, "Oh, I recollect now, the first *relays* were not made at the factory, but by a workman off the premises, and the reason I now know his name is that he (the workman namely) called upon me, in company with Mr. Guy, at the end of 1860, about these very relays."

I have only to say as to this, that Mr. France did not see Mr. Jones until long after the first pneumatic arrangement was completed and delivered.

If Mr. France refers to his order, or the accounts of the company, he will find that Mr. Andrews ordered seven of these pump arrangements, and that after Mr. Andrews left he (Mr. France) ordered four more—the last of which was delivered in March, 1861. My assertion, therefore, is perfectly correct.

I am, Sir, your obedient servant,

Windsor-terrace, City-road, 25th February, 1864. G. GUY.

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—I have made inquiries, and find, in confirmation of my letter of the 30th ult., that three of Mr. Andrews' double stream Morse instruments were mounted at Heligoland on the 22nd December, 1860; three others having been mounted at Flensburg about a fortnight previous—therefore subsequent to the 27th October, when the first pump relay was completed.

I am, Sir, your obedient servant,

Cromer, Feb. 23rd., 1864. F. HARWOOD.

THE TELEGRAPH CLERKS' PROVIDENT FUND.

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—I was much grieved when I read in your last number that, at a meeting of the *employés* of the Magnetic Telegraph Company, after considerable discussion, a resolution was passed to the following effect, viz.:—"After carefully investigating the scales of payment, remuneration, and the rules, regulations, &c., of the 'Telegraph Clerks' Provident Fund,' this meeting is of opinion that the benefits to be derived therefrom are not adequate to those offered by other societies of a like nature, and that the numerous technicalities and requisitions introduced into the said rules debar the majority of telegraph clerks from becoming members." Having read carefully the rules, regulations, &c., I cannot conceive what kind of arguments could have induced those present at the meeting to arrive at the conclusions they appear to have done. One might have reasonably expected that a society, patronised by some of the leading men of the day, and by many of the most influential directors of telegraph companies, would at least have paid attention to its rules, regulations, &c., so as to confer the greatest possible benefit upon those for whom the fund was instituted. It is to be feared that this unfortunate resolution on the part of the meeting is only another instance of the senseless jealousy and rivalry which exists between the *employés* of the various companies. Every attempt to bring them together to co-operate in some action for mutual advantage has failed. It is all *repulsion* without *attraction* or adhesion. Why is it? I believe the question has been fully answered by your correspondent, who signs himself as "One of the Least," in your last number.

Yours, &c.,

A SHAREHOLDER.

SELF-HELP.

To the Editor of the TELEGRAPHIC JOURNAL.

Dear Sir,—Permit me, through the medium of your valuable paper, to reply, in a brief and concise manner, to a letter in your last week's number, signed "One of the Least."

I read with pleasure the remarks, and also the scheme for establishing a *recreation* club for the telegraph *employés* in general. I firmly believe such a club could be established, but it requires the assistance and support of the directors of the various telegraph companies. I regret that hitherto a friendly feeling between the *employés* of the telegraph companies has not manifested itself, but the time for improvement has arrived. The clerks of each company have tried to establish an institution for themselves, and by doing so have failed.

The success of such an undertaking depends solely on strength and union, and I trust the time is not far distant that a similar club will be established. I feel confident that the directors of the various companies would assist their *employés*, and the scientific men connected with telegraphy would enhance the value of the institution by giving lectures occasionally, by which the members would become better acquainted with the noble science of telegraphy, and would feel more interested in the performance of their duties.

Let us, therefore, hope that, with the aid of our friend, Mr. Editor, the scheme in contemplation may be crowned with success.

Feb. 23rd., 1864. A FRIEND.

TELEGRAPHIC FEATS.

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—I have read with much interest the paragraphs and correspondence in your journal on the subject of the speed of the respective instruments used by the existing telegraph companies. Perhaps my opinions as an old telegraphist, as a manipulator of considerable experience and practice, and I may add (without being egotistical) of speed and general ability in this department, will assist in the solution of the question of their merits. A good and intelligent manipulator is the best judge of the powers of the instrument he works, and if he is capable of working those used by the two large companies, his judgment of their merits is the more trustworthy and correct. Others who do not understand the ramifications of transmitting business are liable to be misled by appearances, and to be blinded to real facts by their enthusiasm and admiration. They are told of "feats," which, to an old clerk, are of hourly occurrence, and at which he quietly smiles. In fact, I agree with the bell clerks at Glasgow, that the speed of transmission of the Queen's speech was slow, excepting that of the Magnetic Company (forty-eight words per minute).

The double needle requires two wires. The difficulty of watching and of catching the usually feeble and spasmodic clicks of two needles necessitates great care, great practice, and a diminution of speed; the handles by which they are worked are cumbersome, and soon tire the arm of the clerk. There is the possibility of a difference of signal-power on the separate needles, according to insulation, manufacture, &c. They are a delicate instrument, and a writer is required. On the other hand, they are advantageous, inasmuch only as in case of stoppage of one wire the other can be worked (if it be preserved) by the Morse code. A clerk on the double needle can send at a great speed, but the reader cannot follow the needles above a maximum of about thirty-eight words per minute. The single needle, from the nature of its construction and code, is very slow and uncertain, its maximum speed being about fifteen words per minute.

The Morse instrument is most decidedly the king of instruments, taking into consideration all its properties of application, although its speed is poor comparatively. It allows clerks of different nations and tongues to converse in a language (so to speak) of itself—telegraphic and universal. It will work long lengths of wire, and is peculiarly adapted to submarine telegraphy. It records every stroke made.

There is, however, one instrument which, in my opinion, for home work surpasses all these. I refer to Mr. Bright's bell used by the Magnetic Company. Often I have been surprised to see so little said of it. Very few really understand its merits. The others have all, more or less, and at one time or another, received their meed of praise and attention; yet this beautiful and useful instrument is unnoticed. I leave it to others more competent than myself to explain the principle and nature of its construction: with its powers of working I am well acquainted. By means of the two bells the ears perform the office of the eyes with the needle systems, and the eyes are at liberty to attend to the "caligraphy." Whilst hearing the signals the clerk can write down the despatch; and so firm and distinct are the beats of the hammers upon the bells, that there is little fear of error. The attention of stations is sooner gained; the confidence is greater; signals, by means of the relay, are stronger; the services and wages of a writer are dispensed with; the speed is greater; the work easier, and less painful; the eyes are not taxed injuriously; many little things can be attended to whilst receiving.

"An Old Double Needle and Morse Clerk" asks, "Will the bell clerk undertake to say he never feels doubtful respecting the correctness of a message he may have received?"

An "Old Bell Clerk," in return, asks him, "Does he not sometimes gaze in bewilderment at the confused mass of dots and bars which some blundering clerk has sent on his *recorded copy?* Is not the receiving slip, or recorder, subject to the same irregularities, messes, and mistakes which the sender may make by the impression of his key, &c.? and, whilst the Bell clerk by *one tap of his key* can stop and have a fault corrected in an instant of time, the poor recorder has to 'finish his yarn' before he can do it!"

The Bell affords facilities for quick exchanges of questions and answers and ideas. Correction or repetition is obtained with *one tap* of the key by expert clerks. Conversation and quick stoppage and renewal of work is scarcely possible with the Morse. The maximum of speed with the bell instrument is about 50 words, of average length, per minute—35 and 40 words is common throughout the day and night on busy circuits in any of the Magnetic Company's offices; and one clerk, I assure you, often takes two or three columns of matter, writing for himself, and *revising as he goes on*, sending copy direct to news room or paper, decent and respectable, at 30 and 35 words per minute.

The needle instrument, used by the Magnetic Company, on the principle of which the bell is an improvement, is also a simple, useful, and speedy instrument, superior to the single and double needles mentioned before.

Your correspondent "P. D. Maxwell," and others who have taken part in this discourse, as well all as your readers generally, may, perhaps, find the above interesting—perhaps instructive; and, if this be the case, I am content that I have not wasted your space in giving a close and *impartial* examination into the subject, and which is the result of experience and labour in telegraphic concerns. W. H. N.

Stockton, Feb. 23rd., 1864.

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—As you have already given publicity to several communications relative to the degree of speed with which intelligence can be transmitted by different telegraph companies using different apparatus, I hope you will be kind enough to allow me space for a few remarks upon the same subject. I am a practical telegraph clerk of some years' experience in single and double needle and Morse working, obtained in the services of the Electric and International and the United Kingdom Telegraph Companies. Never having been in the Magnetic Company, I cannot speak positively of either their instruments or working; but I quite agree with your remark applied to a performance of one of their clerks, who is reported to have received the Queen's speech (writing for himself) at the rate of forty-eight words and a fraction of a word per minute, which certainly is, in my humble opinion, "truly marvellous;" an opinion I am inclined to think that will be shared by a large majority of telegraph clerks. With regard to quick working, it is really more a question of clerks than instruments. And the transmission of speeches is by no means a fair or full test of the merits of either so far as general working and utility is concerned, as the rate of speed attained in transmitting a speech would offer a wide contrast to the ordinary rate at which messages and general telegraph work is transmitted, no matter what instruments or clerks be employed, for this reason: a speech is a straightforward piece of work for the telegraph clerk; it is very readily understood, and generally of such a character that any doubtful word can be easily determined or supplied by the sense of the matter (a very great boon to needle or bell clerks), in addition to which it admits of much abbreviation. With ordinary messages it is altogether different. In these the telegraph clerk has to encounter all the technical terms used in the various trades and professsions, names of persons, ships, places, &c. (many of which are foreign), and a host of other matters, some of which are quite unintelligible to the telegraph clerk, as, for instance, messages sent (as many are daily) in a code known only to their senders and receivers themselves; and it is in dealing with this general business that the Morse proves itself so superior to all other instruments; and it is here also that the needle and bell instruments fail to keep up even a fair or proportionate speed with their speech working, &c.; and I will undertake to say that the bell clerk reported to have performed the "truly marvellous" feat of receiving and writing for himself forty-eight words and a fraction per minute, would find a great (and I believe an insurmountable) difficulty in reaching an average of half forty-eight words per minute if occupied with such work as I have just alluded to. My intention, however, is not so much to say anything against the bell instruments as it is to say something for the Morse, which for accuracy and general utility is undoubtedly and deservedly the first and best instrument of the day, for no matter what language or form is employed by the telegraphing community, it is all the same when written in Morse, and a tangible record is left for future reference if required. I do not mean to say that English clerks not understanding French or German, for instance, could take messages in those languages on Morse as quickly as if they were in English, but I do mean to say that the Morse would in such a case possess an immense and obvious advantage over either bell or needle instruments. The fastest Morse working I have seen has been in the United Kingdom Telegraph Company, whose form of apparatus is a great improvement upon that used by the Electric and International Telegraph Company—when I left at least—(so far as quick working is concerned I can speak positively); as the manipulating key in the latter company used to require about six times the "play" those used by the United Company do, and as a man can walk a short distance quicker than a long one, so a telegraph clerk can mark quicker with a key of "short play" than with one of "long play."

Yours obediently,

Newcastle-on-Tyne, Feb. 20th, 1864. R. A.

AERIAL WORK.

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—In your impression of last week, referring to our aerial work in Huddersfield, you make an inaccurate statement, or rather leave your readers to believe that a somewhat serious expense has been incurred by my company through the accident to the contractor's tackle in fixing bracket to chimney. The entire cost of making good all such damages did not exceed £6.

I am Sir, yours very truly,

Pro JOHN DOHERTY, District Superintendent.

The United Kingdom Electric Telegraph Company (Limited),

Manchester, Feb. 23rd., 1864.

IMPORTS OF GUTTA PERCHA.—The quantities imported into the United Kingdom have fallen off within the last three years. In 1860 they were 21,321 cwts.; in 1861, not more than 19,749 cwts.; and in 1862, 18,284 cwts.—so that, comparing the latter with the former year, a decrease appears of 3,037 cwts., or about 14 per cent. British India contributed in 1862 four-fifths of the total supply. Holland furnished 1,736 cwts.; Borneo 1,163 cwts.; and all other places made up an additional sum of 858 cwts. The total value of the imports in 1861 was £130,602; in 1862, with a decreased supply of 1,465 cwts., it advanced to £195,399. The average price in the former year was £6 12s. 3d. per cwt., whereas in 1862 it ranged from £10 8s. 10d. to £11 1s. 2d. per cwt.

TELEGRAPHIC NEWS.

THE *Malta Times*, of the 11th of February, publishes the following information:—"The Otrante and Avlona Telegraph Cable.—We understand that telegraphic information has been received in Malta from the Chief Inspector of the Italian Telegraph Administration that the vessel with the cable is now lying at Brindisi, and is only waiting for fine weather to commence the submersion of the cable."

THE OTRANTE AND AVLONA CABLE.—This expedition, in charge of Mr. G. Henley, arrived at Brindisi on or about the 26th of January last. After having been detained in that port sixteen days by stress of weather, they proceeded to lay the cable from Otrante, but the weather became so boisterous, causing the ship to drift, that before the point on the other side had been reached the whole of the cable was found to be submerged. The contractors intend to complete the undertaking so soon as the weather moderates.

TELEGRAPH TO INDIA.—The Convention between the English and Turkish Governments, relative to the operation of the new telegraph to India, which is to pass through the Ottoman dominions, was signed on the 17th instant.

INDIAN TELEGRAPHS.—The progress of the great lines of railway in British India has naturally been followed by the extension of the electric telegraph, as has been the case at home. We understand that a contract has been entered into by Messrs. W. M. Warden & Co., of Great George-street, Westminster, for the construction of a line of telegraph on the Jubalpore branch of the East Indian Railway Company, the whole length being 250 miles. The poles, wires, insulators, &c., are of the best materials and improved forms. The batteries to be employed are Muirhead's sulphate, which have already proved themselves exceedingly well adapted for hot climates, being universally adopted on the telegraph lines in India.

THE PACIFIC TELEGRAPH COMPANY.—This company's line is 1,700 miles in length, and extends from Chicago to Salt Lake city, Utah territory, where it is connected with the Californian lines. The line is divided into three circuits: the first, extending from Chicago to Omaha city, Nebraska territory, is 600 miles in length; the second, from Omaha city to Fort Laramie, is also 600 miles long; and the third, from Fort Laramie to Salt Lake city, is 500 miles long. The whole line is constructed with No. 9 iron wire and cedar posts, set 16 rods apart, and is one of the best working circuits in the United States. On the first section of the line 60 grove cells are used as line battery, and on the second and third sections 50 cells. Chicago works *direct* with Salt Lake city by means of repeaters (relays) at the two intermediate stations; it also occasionally works direct with San Francisco, which is 900 miles west of Salt Lake city—bringing the total length in direct communication to 2,600 miles. The number of operators employed are—two at Chicago, three at Omaha city, two at Fort Laramie, and four at Salt Lake city; all which are first-rate workers on the instrument in use—the Morse, read by *sound*, with the American alphabet, which is shorter than the European one.—(*Special Correspondent.*)

MALTA AND ALEXANDRIA CABLE.—By the arrival of the last mail from Malta, we are placed in possession of the following intelligence:—Her Majesty's screw corvette *Cossack*, 20, Capt. W. R. Roland, was under orders to leave on the 16th instant for Corfu. It was understood that she was to take up Major Schaw, an officer of the Royal Engineers, who was expected, on the night of the 15th instant, in the *Psyche*, from Marseilles, to take part in the destruction of the fortifications of Vido and some of the other works in the island of Corfu, as already mentioned in another paragraph in this journal. The expedition for the repair of the Malta and Alexandria cable started on Saturday night, the 20th instant, for the neighbourhood of Benghasi, where the injury was believed to exist. The chartered steamer *Fanny Lambert*, Captain Christopher, carried with her a sufficient quantity of cable and all the necessary apparatus for this operation. Mr. Canning, engineer, and Mr. De Sauty, electrician, have preceded her with an efficient staff. Mr. Gibson, the Government inspector, accompanies the expedition on behalf of the Home Government, and Lieut. Drew, R.N., from Her Majesty's ship *Hydra*, is to assist in the navigation of the vessel. Her Majesty's screw steamer *Surprise*, 4, Capt. N. H. Whyte, had proceeded with the *Fanny Lambert* to attend upon her, and render any assistance that might be required. The local military submarine telegraph in the grand harbour between Forts Ricasoli and St. Angelo has been for some time past out of order, and considerable inconvenience has been caused thereby to the garrison. Communication was re-established in December, but soon afterwards (in January) a steamer, dragging her anchor, again severed the line. Through the exertions of Mr. Gibson advantage was taken of the presence here of the repairing staff of Messrs. Glass, Elliot, & Co., and there was every reason to believe that the cable had now been effectively repaired. [On going to press, we learn that the cable has not yet been repaired.]

THE GLOBE TELEGRAPH COMPANY (LIMITED).—The directors of this company have applied for Parliamentary powers to purchase various patents granted Mr. Henry Wilde, of Manchester, for improvements in electric telegraphs, and for carrying out a system of private electric telegraph communication between the Government offices and other important public and private establishments within the United Kingdom of Great Britain and Ireland by means of such instruments.

THE PERSIAN GULF TELEGRAPH.—Bombay, January 22.—The *Marian Moore*, which arrived there on the 22nd of December, 129 days from London, had left for Gwadur, on the Mekran coast, in tow of Her Majesty's ship *Semiramis*. The *Kirkham*, with 185 miles of the cable, including six miles of heavy shore end, reached Bombay on the 13th instant, 120 days from London, and goes to Gwadur, towed by Her Majesty's ship *Zenobia*. Sir Charles Bright had left for Kurachee, with Colonel Stewart, in Her Majesty's ship *Coromandel*, and will meet the cable ships at their destination about the 29th instant, when the submersion of the line will commence from the *Kirkham*, which will be towed, after landing the shore end, in a westerly direction, towards Ras Jask. When the whole of her cable has been laid from the three iron tanks in which it is coiled, the end will be passed on board the *Marian Moore*, and the paying out will be continued from her as far as Ghubeht Ghazirch, a sandy inlet near Cape Mussendom, and about 12 miles from Khasab, where the station is prepared. From this point the cable will be laid from the *Assaye* towards Bushire, and the *Tweed* will supply the remainder to the head of the Gulf. It is expected that the work will be completed in three months. The following is an extract from a private letter, dated Bombay, 27th January, and arrived by the last mail:—"The *Marian Moore*, the first of the cable ships, arrived about a week before us. The *Kirkham* arrived on the 13th instant. The *Assaye* and *Amber Witch* ought now to be here; but of these we know nothing recent. The *Tweed* seems likely to be in first, she having been seen at Galle on the 25th instant. On the 21st instant the *Marian Moore* and *Kirkham*, accompanied by three other steamers, left Bombay, with Colonel Stewart and Sir Charles Bright, the staff for laying, and also such of the clerks as had before arrived, for Gwadur, between which place and Mussendom it is proposed to lay the first section of the submarine line."

RAILWAY TRAIN SIGNALS.—It appears that the French Minister of Public Works has addressed a circular to the directors of railway companies, recommending measures, which it is hoped, when carried into effect, will add greatly to the comfort and security of travellers. In the first place the Minister has decided that the regulations by which the guards of trains are required to be in constant communication with the engineer shall be strictly carried out within a period of three months.

UNITED KINGDOM TELEGRAPH COMPANY.—This company having extended its wires to Stockton-on-Tees, Sunderland, and Newcastle-on-Tyne, messages of twenty words can now be forwarded to those towns from the metropolis for 1s.

THE UNITED KINGDOM TELEGRAPH COMPANY opened their offices for public business at Stockton, Sunderland, and Newcastle, at 5 p.m., on Thursday, Feb. 23rd. This company have experienced much difficulty in their erections in the north-east district from opposition by landowners, &c. At Eland they were compelled to remove the poles in the streets after they had been planted and finished in a style most creditable to the company. In several other parts also poles had to be removed. During the heavy gale of wind on the 13th and 14th their wires across the Tyne were blown down, doing considerable damage to property. They have succeeded in obtaining the patronage of most of the important telegraphing merchants by securing them as shareholders.

WE are happy to have to announce that Mr. George Sheward, one of the directors of the London District Telegraph Company, and chairman of the board of management of the Telegraph Clerks' Provident Fund, was elected a director of the London and North-Western Railway Company at the last general meeting of the company.

CAPTAIN H. SCHAW, Royal Engineers, who is at the head of the Electric Telegraph and Photographic Schools at Chatham, has proceeded, by order of the Government, to Corfu, for the purpose of superintending the demolition of the fortifications in that and the neighbouring islands.

SUBMARINE TELEGRAPH COMPANY.—The messages for Denmark, Sweden, and Norway, can now be telegraphed to Warnemunde; from thence they are despatched by boat, leaving every other day (on the odd days commencing from 13th inst.), to Ystadt, from which place they are telegraphed to destination. The boat transit occupies about twelve hours. Messages are also sent by post from Ystadt to place of destination. During the month of March the boat will be despatched on even days.

MAGNETIC TELEGRAPH COMPANY.—At a special meeting of the Improvement Commissioners for the town of Huddersfield, held in the board-room, on Wednesday, the 16th instant, the Chairman (Mr. Sykes) read a letter he had received from the Magnetic Telegraph Company, stating that they were about to establish a branch at the shop of Mr. Wood, New-street, and requesting permission from the commissioners to carry their wires across the streets if they could arrange with the owners of the property for leave to fix their wires. Permission had been given in Manchester and other towns. The Chairman said an application of a similar nature had been made by another company some time ago, and it was granted so far as the commissioners were concerned. He supposed he might write and give the permission. —Mr. N. Learoyd said he thought so.—Mr. Clough said it was a matter that required a little consideration. If they had their wires up twelve months they established a right to have them up.—Some conversation took place on the point, and ultimately it was agreed that the matter should be referred to the paving and drainage committee, it being understood that the special Act of the company should be referred to, to see if, by giving the permission requested, the commissioners would sanction anything that might injuriously affect the ratepayers; if not, the permission should be granted.

TELEGRAPHIC INSTRUMENTS.—At the Seventh Annual Conversazione of the Huddersfield Literary and Scientific Society, held in the Philosophical Hall and Assembly Room, on Thursday evening, the 18th instant, a number of telegraphic instruments were exhibited, supplied by two telegraph companies—the Globe and the United Kingdom. The former exhibited their new private telegraphs, which were very interesting to the spectators, as the message forwarded could be read by any one as it was spelled on a dial encircled with the letters of the alphabet. But the instruments exhibited by the latter proved the most attractive. One of them, "Hughes' type-printing telegraph," was in connection with Manchester, and messages were continually sent and received during the whole of the evening, and all of them were clearly printed on paper, a long strip of which, something like an enormous roll of tape, was placed in a cylinder near, and regularly fed the machine. The specimens of printing and telegraphy produced by this instrument were sought after with the greatest avidity, and an animated conversation was maintained with the operator at Manchester for about three hours. An ingenious application of electricity as a fire alarm was also exhibited and was much noticed.

ON Tuesday, the 16th instant, an admirable lecture was delivered at the Athenæum, Exeter, by Mr. Bartholomew, on "Electric Telegraphs." His intimate acquaintance with the subject, theoretically as well as practically, renders Mr. Bartholomew a lecturer always heard upon this and kindred subjects with profit and pleasure; and we are pleased to find, from the testimony of those who attended at the Exeter Athenæum, that more was learnt respecting this most interesting, although little understood subject than had ever been the case before. Mr. Bartholomew made special allusion to the Atlantic Telegraph, which he was well qualified to do, having been connected with it from the first starting of the expedition in 1856 to the close of its successful submersion in November, 1858. The reference made to this great undertaking proved a point of great interest to Mr. Bartholomew's audience. We understand that Mr. Bartholomew has some idea of visiting the north, and we think the good people in Scotland will do well to avail themselves of the opportunity which may be presented of hearing something about telegraphy from one who has spent nearly 20 years in the profession.

MISCELLANEA.

ELECTRO-MAGNETIC ENGINE.—We extract the following from a New York paper. Our readers must attach their own value to the statements made:—Captain John Reeves, of New York, is the inventor and patentee of an electro-magnetic rotary engine, for producing motive power by electricity, to any extent and for any purpose required. The inventor, in his experiments, has discovered, and is now prepared to verify the fact, that electricity can be diffused over surfaces to the extent of hundreds of superficial feet, and thereby cause an electro-magnetic attraction, which acts on, and sets in motion, the most powerful machinery for producing motive power; and this at a most reasonable expense for material consumed. The method on which the inventor founds the principle for producing and augmenting motive power by electricity is peculiar in its machinery, but comparatively similar in its nature to that by which other elements are brought into practical use—that is, the greater the area of surface exposed to the action of the motive or first cause, whether it be wind, water, steam, or electricity, the greater the effect produced in motive power. In regard to the expense, the inventor makes this comparison—In extending the area of a surface in a steam-engine to increase the power, the momentum being the same, the ratio of expense will increase in proportion. But electricity, being of a different nature, when the area of surface is extended, extra power is obtained, with a diminishing ratio of expense. For instance, suppose it costs 1·25 dol. per horse power for the material to keep a 50-horse power condensing marine steam-engine at work for 24 hours, and the area of surface in the piston is extended sufficiently to produce 100-horse power, the cost per horse power for producing the additional 50 would be equal to that of the first 50. But suppose the cost is 10 cents per horse power for material to keep a 50-horse marine electro-magnetic rotary engine at work for 24 hours, and the area of surface is extended to produce 100-horse power, the additional 50-horse power would be obtained at a quarter less cost than the first 50; therefore, the whole expense would be greatly reduced. A marine electro-magnetic rotary engine, and all its accompaniments for a six months' cruise, would not occupy more space in a vessel than a marine steam-engine of equal power, saving the room now required for furnaces, boilers, coal-bunkers, &c. A vessel to be propelled by electricity can be built with one-fourth less capacity, at less expense, with finer lines for speed, carry equal burden, and in every way possess superior qualities to one built for being propelled by steam. Again, a vessel propelled by electricity can be entirely closed up when required. This will make it available for arming in a peculiar manner, either for assault or defence, and navigable submerged or on the surface of the water. This invention is destined to make great changes, not only in our river and ocean navigation, but also in railways of every description. The inventor has a working model at the Capitol, with plans of different descriptions, which he is preparing to exhibit to the Government.

Improvements.—During the year 1863 no fewer than 53 patents were sealed for improvements in the manufacture of telegraph instruments, insulators, cables, &c.

Substitute for Gutta Percha and India Rubber for Insulating Purposes.—At a late meeting of the French Academy of Sciences, M. Serres gave an account of the Valata, a shrub which abounds in Guiana, and affords a juice which he asserts is superior for many purposes to gutta percha, but more especially as an insulating material for enveloping telegraphic wires. The milk or juice is drinkable and used by the natives with coffee. It coagulates quickly when exposed to the air, and almost immediately when precipitated by alcohol, which also dissolves the resin of the Valata juice. All the articles made with gutta percha can be made with the sap of the valata juice, and it has no disagreeable smell. When worked up it becomes as supple as cloth and more flexible than gutta percha. M. Serres exhibited a number of articles manufactured of Valata milk that at the present time it seems, from M. Serres' account, have not become of commercial export.

"Deflections," or "Earth Currents."—Occasionally, especially during the aurora borealis, strong currents, sometimes steady, at other times changing their direction very rapidly, appear in the wires. These currents are not caused by atmospheric electricity, for they cease if a wire be disconnected at one of its ends, and they appear equally in buried as in suspended wires. They seem rather to be caused by currents flowing from one part of the earth to another, which enter the wires by one of their earth connections, and leave them by the other when the currents happen to be passing in that direction. The wires are constantly traversed by these currents, but it is only at times that they attain sufficient force to affect the apparatus. They appear most frequently, and have greatest power on the lines lying N.E. and S.W.; but it appears that the direction of the current changes with the hour of the day, so that one line may be more strongly "deflected" in the morning, another in the afternoon. The current has frequently been seen to leave one circuit and to appear upon another previously free. Communication may be kept open by means of a magnet, to counteract the effect of the current. But when deflections are very strong and very variable in direction, the best method is to disconnect two wires from earth at both ends, and to use one as a *section wire* to the other in place of the earth.—*Culley's Handbook.*

Magnetic Phenomenon.—Dr. A. von Waltenhofen has communicated to *Dingler's Polytechnisches Journal* an account of a curious magnetic discovery which he has recently made. It is a well-known fact that the magnetism of an electro-magnet does not entirely disappear with the cessation of the magnetizing current. Dr. A. von Waltenhofen has, however, observed that the amount of this residual magnetism, as it is called, is dependent upon the manner in which the current is interrupted. If this interruption take place suddenly, the residual magnetism is much less than when it takes place gradually. A still more interesting circumstance has been observed by him—viz., that the residual magnetism obtained by suddenly breaking a very strong current, is sometimes of an opposite nature to that previously existing in the electro-magnet. This fact, which he has hitherto only noticed in very soft iron, is of great interest, inasmuch as it furnishes a new and simple proof that magnetism is not caused by the separation of two fluids, but by the motion of magnetic molecules, to which is opposed a certain amount of frictional resistance. With much ingenuity he compares the state of each magnetic molecule of the electro-magnet to that of a spring which is bent back. If the spring be suddenly released, it will return very nearly to its original position, or even go beyond it. On the other hand, if it be released gradually, it will stop at a point still further removed from its original position.

Rapid Communication in 1846.—(From an old Magazine.)—From the description given of Mr. Bain's invention, it will be seen that the rapidity of communication by it is limited by two circumstances only: first, the time required to punch out the holes in the roll of paper of the transmitting apparatus before committing it to (may we not say ?) the press; and, second, the number of intermissions of the electric current which can be effected in any given time—one intermission being requisite for every letter or sign. Now, the time required for the first part of the process must depend on the number of letters or signs which it is in the physical power of a clever hand to punch out in a given time, which can scarcely exceed on the average 100 a minute; but the passage of the electric fluid is so instantaneous (faster than lightning) that we make no doubt from 500 to 1,000 intermissions in a minute may be readily effected in the way proposed by Mr. Bain. Supposing, therefore, a communication be once punched out in paper, and the paper to be committed to the transmitting apparatus, it will require but a few minutes to convey that communication to any distance however great, and that, too, in as complete a state as any letter, despatch, circular, or pamphlet is now conveyed bodily by post. We foresee the perfect practicability in this way of all the leading articles of the *Times* (*ex gr.*) being reprinted and republished in Liverpool, or Glasgow, or Edinburgh simultaneously with their publication in London! It would only be necessary, in order to effect this incomparable desideratum, that there should be placed by the side of each compositor a man, with a set of punches and a roll of paper, to punch as fast as the other composed—and that, when a column was completed, it should be sent off to the electric telegraph-office, to be transmitted to Liverpool, Glasgow, or Edinburgh, there to be rendered from the telegraphic characters into the ordinary characters of our mother tongue, reprinted and republished. Has any other plan of electro-telegraphic communication yet proposed offered advantages equal to this? We believe not. Suggestions, pointing to such a plan, have, we are aware, been thrown out before now; but Mr. Bain has, at all events, the unquestionable merit of being the first to turn to practical account a principle which all the other able men occupied with the same subject have practically neglected.

TO CORRESPONDENTS.

As information respecting Improvements, Extension of Lines, and Progress of New Undertakings will at all times be most acceptable, we hope that our readers will kindly render us assistance in our efforts to establish a Journal worthy in all respects of the great interest it seeks to represent, by furnishing us with brief notices of events and occurrences in connection with Telegraphy.

Letters relating to Advertisements are to be addressed to the Publishers. All other letters and communications to be addressed to the Editor of the *Telegraphic Journal*, 5, Suffolk-lane, Cannon-street, London, E.C.

The *Telegraphic Journal* can be had of Messrs. Smith & Co., Strand; Messrs. Dawson & Co., Cannon-street, E.C.; Messrs. Kent & Co., Paternoster-row, London. Messrs. Heywood & Co., Manchester; at the various railway stations; and of all news-agents, &c., &c.; or it can be supplied, if preferred, direct from the Office on the following terms:—

	s.	d.
Quarterly	4	4
Half-yearly	8	8
Yearly	17	4

TO ADVERTISERS.

The *Telegraphic Journal* is the most effective medium for inventors, patentees, contractors, manufacturers of insulating materials and electrical apparatus to submit their various specialities to the consideration of secretaries and managers of telegraph or railway companies, and other persons engaged in electrical and telegraphic pursuits.

Clerks, assistants, manipulators, and instrument makers, seeking employment, &c., will find the *Telegraphic Journal* a ready means of making known their requirements.

Advertisements must be delivered to ensure insertion before Seven o'Clock on Thursday evening in each week. The charges for Advertisements are—

	£.	s.	d.
Whole page	4	4	0
Half ditto	2	10	0
Quarter ditto	1	7	6
Four lines and under (single column)............	0	3	0

Single Advertisements from the country must be accompanied with stamps in payment.

AN INSTITUTE FOR TELEGRAPHISTS.

A nation's progress is found to be in exact ratio with the prosperity of its home institutions; and England's pre-eminence in the arts and sciences may be attributed in a great measure to the facilities which exist for communication between her experimentalists and men of science. The country abounds in Societies of Arts, Institutes of Engineers, Architects, &c., Unions for all purposes conceivable—indeed, every profession is represented by some organisation except Telegraphy. Why is this the exception? Is it so unimportant—so juvenescent—as to be unable to sustain an Institute wherein all engaged in telegraphic pursuits may meet periodically for discussion, and to take counsel together as to the best means of realising any important project? Or is it that there is so much of the *meum* and *tuum* animating the men engaged in the art, that they cannot be at one in the realisation of so important a scheme? But perhaps in these reflections we are aiming beyond our object. We purposed in the outset a few considerations as to the practicability of establishing an Institute for Telegraphists—liberal in its general features, and offering advantages to all persons engaged in this branch of science.

No difference of opinion can exist as to the desirability of friendly communication between the employés of telegraph companies, or as to the importance of strengthening by union the interests of the persons engaged in telegraphy, on whose behalf we speak, rather than for scientific or professional men.

Hitherto, all efforts tending to this end have been frustrated by senseless jealousy and narrow-mindedness. The various companies are competitive in character, and it would seem that this trait in the organisations determines in degree the conduct of the employés; and, as each company is "limited," we may, perhaps, be able to account for individuals on the several staffs limiting their friendly relations to the amenities of society. This condition of things will admit of great alteration. Class-exclusiveness has always seriously retarded improvements; and now that the telegraphic service of the country has become so important, it behoves all those who are interested in its progress to promote a greater cordiality than has ever existed between telegraphists—from the manager to the messenger.

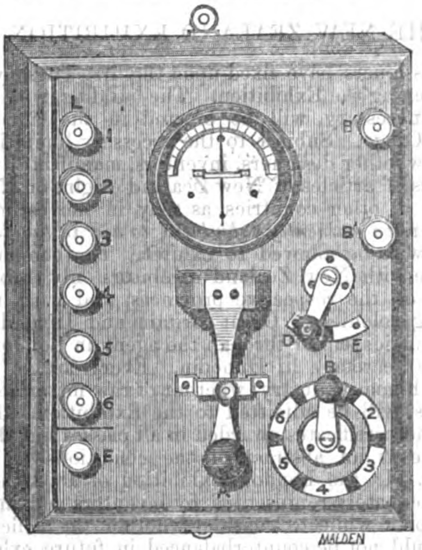
How to attain this object is the question! Institutions have sprung up among the employés of the many companies in London, and have been productive of good; but, like Pepper's Ghosts, they are not substantial—they do not last long. The elements of cohesion are wanting, or, as one of our correspondents says, referring to this state of affairs, "it is all *repulsion* without *attraction*." It is time that this discordance ceased, and that harmony prevailed. There is need of a fraternal union, which might be materially advanced by the establishment of an Institute—some centre of attraction for all. Let us, then, consider the possibility of meeting this requirement. The greatest difficulty likely to be experienced in carrying out a scheme of this kind is that of awakening and sustaining an interest among those who should be the readiest to perceive the advantages of co-operation. Mankind is very selfish, and it may be politic to avail ourselves of this distinguishing feature in order to further our legitimate designs. This consideration brings us to the point; and we venture to suggest that, were the Telegraph Clerks' Provident Fund, the Dramatic and Recreation Clubs, Discussion and Literary Classes, in connection with each company, incorporated under a representative management—vigorous in its operations and progressive in character—an Institution might be inaugurated which would be creditable to the employés and a honour to the service. The patronage enjoyed by some of these local unions—at present comparative failures—if concentrated, would enable a committee to submit comprehensive measures personally advantageous to the members, and thus kindle an interest among all classes in the welfare of the association. The cost of management might be at the minimum, the benefits to be derived at the maximum, and then we should have the pleasure of recording more favourable resolutions than those arrived at in a recent meeting of the Magnetic Company's employés (when the claims of a very useful organisation were submitted for consideration), and which were duly published in our columns. A work of this kind only needs a commencement; it might be initiated with grace by the secretaries of the several clubs and funds before enumerated. If begun in a dispassionate spirit, and carried out in a business-like manner, it will ensure the support of all persons engaged in telegraphy, and cannot fail to meet with patronage and approval among shareholders, directors, and others, whose aid will doubtless prove acceptable.

THE TELEGRAPH CLERKS' PROVIDENT FUND.

We have to announce, with great pleasure and satisfaction, that Her Royal Highness the Princess of Wales has graciously become the patroness of the above excellent institution. Her Royal Highness has also contributed a donation of £10 10s. towards the Fund. We are glad to find that the Society continues to gain in number and strength, thanks to the exertions of its indefatigable secretary, Miss Oppenheim, and that already its advantages have been experienced by members incapacitated by illness to follow their occupations. A case has been brought before us this week of the widow of one who died in the telegraph service, and who is left, with her infant children, in a state of distress and helplessness. We find that Government Annuities, not exceeding £30 per annum, may be contracted through the Society, the annual premiums for which may be paid by monthly or quarterly payments, and that a husband and wife may each hold any of these annuities. We append a few particulars respecting this feature of the Fund, showing the advantages to be derived by the purchase of annuities:—If the annuity be purchased, and the money required for the same shall be actually paid into the account of the Commissioners at the Bank of England or Bank of Ireland, after the 5th day of January and before the 5th day of April, such annuity will be payable the 5th of July and the 5th of January in every year; if after the 5th day of April and before the 5th day of July, it will be payable the 10th of October and the 5th of April; if after the 5th day of July and before the 10th day of October, it will be payable the 5th of January and the 5th of July; if after the 10th day of October and before the 5th day of January, it will be payable the 5th of April and the 10th of October. These annuities are not subject to the income tax. Our readers will find the subject more fully referred to in the *Telegraphic Journal* of the 30th January, page 59.

SAX'S ELECTRIC COMMUNICATOR.

Under the title of the Electric Communicator, Mr. J. Sax, of 445, New Oxford-street, has devised a simple means of communication between the most distant parts of large establishments, such as banking-houses, offices, hotels, factories, &c. The instrument is much more simple in its details than the electric telegraph, can be readily understood by any person of average intelligence, is cheap in the first cost, and is not liable to derangement.



The entire working parts are contained, as represented in the engraving, in a case 8 in. by 6, by 2 in. in thickness; this can be placed against the wall of an office or other room without taking up any useful space. The two screws marked B′ B′ on the right hand, at the top of the woodcut, serve to secure the two wires from a small galvanic battery, that can be placed in any convenient corner out of the way. The screws marked 1 to 6 serve to attach wires running to the bells in the places to which the communications are to be made; these may be as numerous as required. The screw E is for attaching a wire from the earth, that brings back the return current from the alarm bells, and completes the electric circuit. One "earth," as it is technically called, answers for any number of wires. The circle marked with figures in the right hand lower corner of the cut, represents a contrivance known to electricians as a commutator, by means of which the electric current can be sent in any required direction. On moving the handle B, which now covers the figure 1, to any other number, the current can be sent along the corresponding wire.

Let us imagine a communication required to be made with the workshop or room to which the wire number 5 is carried, and which may be situated any distance away. All that is requisite is to place the handle B over the figure 5, when the battery is in immediate communication with wire 5, and the current can pass in no other direction. On pressing with the finger the knob A, at the bottom of the instrument, the circuit is at once completed, and passes along the whole distance of the wire from 5 to the room in which the bell is situated, returning by the "earth."

In order to render the instrument more serviceable, and to enable it to give a variety of signals, the small handle above the commutator is added—the knob C of which can be moved over either D or E. When in the former position, as is represented in the cut, a single stroke or signal is given on the bell in the distant room to which the message is sent, and this signal is repeated as often and as rapidly as A is pressed down with the finger. On the other hand, when the handle C is moved over E, a continuous alarm is sounded in the distant room as long as A is pressed down. It is obvious that this power of ringing a continuous alarm bell, and also of making any number of single signals, gives a ready facility for devising a code of signs sufficient for almost all practical purposes.

Let us suppose each workman in a workshop to have a number; he may be instantly summoned to the head-quarters by signalling his number; or by sounding the alarm as may be understood, before or after the signals, a boy may be dispatched to the office with an account of the state of his work. Of course a correspondence cannot be carried on as readily as with an electric telegraph, but for the purposes of communicating with the different parts of any large establishment, this simple, inexpensive apparatus has many advantages; its indications can be understood by all, and its cheapness and non-liability to get out of order strongly recommend it.

The object of the galvanometric needle and large dial in the centre of the instrument, is to show the operator that the exact signals he wishes to make are being recorded in the distant place to which he is signalling. When we add that the cost of this apparatus is only from £3 to £4, we think that we have said sufficient to secure its being at once employed in numerous places, where its introduction will be found to effect a vast saving of time, trouble, and expense. The Electric Communicator has been laid down with two bells by Lord Huntingtower, Grosvenor-square.

THE MANUFACTURE OF IRON WIRE.

It is marvellous that so little interest is felt by the public in the development of the telegraphic system. The impetus which it has given to various manufactures could be shown by a comparison of the consumption of *matériel* in the numerous works which have been projected and carried out during the past twenty years. But this is apart from our present purpose. A very general opinion prevails that telegraphy is a morbid, stagnant profession; useful, it may be, but unproductive of trade, lacking interest for the manufacturing community, and failing to develope the resources of the country to any great extent. These fallacies we shall endeavour to dispel at some future time. Our purpose is now to direct the attention of our readers to one of the most interesting manufactures which have received a stimulus from the telegraphic service. Iron wire is used very largely as a conductor in railway, house-top, and over-ground work generally, and is also very extensively employed as a sheathing for submarine cables. Some idea of the extent to which it is applied may be gathered from the circumstance that 3,000 miles of the Atlantic cables of 1857-8, were sheathed in 126 separate wires, equal to 378,000 miles in length. By far the greater quantity of wire used for telegraphic and other purposes is manufactured in Birmingham and Sheffield, but there is reason to believe that several Belgium firms have of late proved formidable competitors to our large contractors. The processes which we are about to describe are those adopted by English manufacturers.

We proceed to a shed containing a smelting furnace, the fire of which, composed of charcoal, is constantly urged by five or six blasts, proceeding from the mouths of as many "tuyeres," or "tew-pipes," as the workmen usually term them. The "blowing engines," which supply the place of the old-fashioned bellows, are moved by water or steam power, and consist mainly of four cylinders, about three feet in height, and nearly equal diameter, open at the bottom. These are supplied with closely-fitting pistons, moving alternately up and down; and as the further (closed) ends of the cylinders communicate with a common air-chamber and blast-pipe, a constant stream of air is thus kept up, and projected upon the glowing fuel through the "tuyeres," which are, in fact, branches from the main pipe. The iron, which is thrown in with the charcoal, is reduced to a liquid state in about three hours, and being allowed to flow out at the bottom of the furnace, by the removal of a plug, quickly fills an oblong trough, prepared to receive it, and becomes a seething bed of molten iron. Cold water, in small quantities, is then sprinkled on it, and the crust formed on the surface is broken by an iron rod. The produce—a flat mass of brittle iron—is afterwards reduced to fragments, to be remelted, and otherwise worked, till it becomes sufficiently tough for rolling into bars. The intermediate processes which effect this change consist of puddling and rolling. The puddling furnace is built much like a baker's oven, with a low division in the centre, and a high chimney at the furthest end. The fuel being placed in the outer, and the iron in the inner part, the flame of the former passes over the latter, and from the form of the furnace exposes it to an intense heat. When melted, the iron is stirred, and occasionally sprinkled with water; the effect of the operation being first to reduce it to a kind of coarse powder, and then, upon the addition of a powerful blast, to cause it to assume a pasty consistence. It is

divided, whilst in this state, into lumps, which are then subjected, either to the pressure of rollers, or the action of ponderous hammers worked by water or steam power. Thus reduced to bars of about thirty inches in length, and three in thickness, and of peculiar toughness, it is ready for being reduced to wire.

The machinery by which this is effected consists of a series of grooved rollers, revolving at the rate of about 350 turns a minute. They are arranged in threes, regularly graduated from the largest to the smallest. Let the reader imagine himself in a large, partially open building, facing these rapidly revolving rollers—a glowing furnace on his right, and, stationed each at his post, a motly group of men and boys, some with tongs, another (a boy) with an iron hook, others behind the rollers—all looking peculiarly active, hot, and ruddy, in the firelight. Suddenly a glowing bar of metal is tossed from the furnace across the paved floor, alighting with astonishing precision at the feet of those who tend the rollers. In an instant it is seized by two stalwart men, armed with the aforesaid tongs, and one of its ends presented to the largest groove in the lower pair of rollers. ~~It is out of sight~~ in a twinkling, vanishing with a sharp crack, and before the spectator has time to wonder whither it has been so summarily sent, behold it appearing at the second groove in the upper rollers, still glowing, but increased considerably in length, whilst its bulk is similarly diminished. Again seized, like a fiery serpent by the tail, it is sent back as before through a still smaller groove, appearing again in an instant from above; but now the length is doubled and trebled, and as it issues from the last rollers in glowing, snake-like gyrations, it is seized by one end and presented to a winding wheel of iron with a broad rim, and converted into a neat coil. The whole of the operations here described, from the tossing of the heavy bar from the furnace, to the coiling it as wire upon the wheel, are performed in little more than one minute, during which the metal is reduced from a diameter of three inches to one-eighth of an inch, and increased from thirty inches to about thirty feet in length. The wire thus formed is comparatively brittle, and would not, on account of its hard texture, be fit for further reduction in size, as this has now to be effected by a different operation termed "drawing." To prepare it for this, the metal must be *annealed*. This is effected by piling a number of coils within a kind of air-tight furnace, in which it is gradually exposed to a high temperature and allowed to cool slowly. After this treatment the wire is found to be soft and pliable, and is taken to the drawing-shed.

Imagine a long table, surmounted by a row of upright iron drums revolving vertically, being put in rapid motion by a steam engine. At the side of each drum is the draw-plate, a mass of iron, faced with steel, of a rectangular form, in the centre of which is a conical hole. The object now to be effected is to reduce the size of the wire, by forcibly drawing it through the hole in the draw-plate, which hole is smaller than the wire itself. The old method was to draw it an inch or two at a time by means of pincers; but as these required to be advanced, so as to take a fresh grip every few inches, the wire was turned out in a very rough manner, presenting a series of indentations wherever the pincers had taken hold of it. The present method is a vast improvement, and leaves the wire not only free from flaws, but highly polished, and of equal diameter throughout its whole length. The process is as follows:—One end of the annealed coil is filed to a point sufficiently acute to allow it to pass easily through the hole in the draw-plate. Having been pushed through as far as it will go, it is seized by a pair of curiously contrived pincers which are attached to a chain, connected with the longest end of a lever, and moved to and fro when required by the action of a cam or eccentric, fixed to the vertical axis of a drum. This drum is not welded to its axis, but is allowed to slide upon it till needed, when, by means of a lever and a treadle, it is brought down upon the eccentric. In this position, two pegs fall into similar holes in the drum, causing the whole to revolve together. The end of the wire being seized by the pincers as aforesaid, the action of the cam upon the lever causes it to be dragged forcibly forward through the draw-plate for a short distance—the pincers, being again advanced by hand, take a fresh grip of the wire nearer to the plate, and the same action being repeated at every revolution of the cam, a sufficient length is drawn to allow of its being attached to the drum, where it is fixed by a screw clamp.

The drum is now lowered, and caused to revolve rapidly by steam power, and the wire, being thus wound upon it, as it issues from the draw plate, is converted into a coil, which is then tied with a short piece of binding wire and set aside for the market. The hole in the draw plate is kept constantly greased, so that there is no longer that harsh grating sound that, in old times, set the spectator's teeth on edge. The whole operation, from beginning to end, is almost noiseless, and with such facility is the wire drawn by the giant force of steam, that a casual observer might suppose the metal to be as soft as lead. The size of the wire being regulated by the hole in the draw plate, the workman has only to repeat the operation with a graduated series of holes, in order to attain any required degree of fineness.

THE NEW ZEALAND EXHIBITION, 1865.

The Commissioners have fixed upon the first Tuesday in January, 1865, for opening the Exhibition. The building, with such annexes as may be necessary, will be erected in the city of Dunedin, province of Otago. Subject to the necessary limitations of space, all persons, whether designers, inventors, manufacturers, producers or possessors of articles of New Zealand origin, or of such others, the produce of other countries, as may in the estimation of the commissioners *be eminently calculated to aid in the development of the colony*, will be allowed to exhibit. The commissioners will communicate with New Zealand exhibitors only through the local committees of the respective provinces, and with those of the neighbouring colonies of Great Britain and Ireland, and of any Foreign countries, either through the agent in London, or directly through the secretary in Dunedin. Every article produced or obtained by human industry, whether of raw materials, machinery, or Fine Arts, will be admitted to the Exhibition. Juries will be appointed and certificates awarded in all classes but the Fine Arts.

The above is an abstract of the conditions of this colonial undertaking. In the London Exhibition of 1862 the telegraphic art was inadequately represented by inventors and manufacturers, and it is worth while to consider whether the deficiency of that occasion should not be counterbalanced in future exhibitions. So far as we have been enabled to observe, there is a disposition on the part of the people to pay attention to any explanation of the operation and uses of the electric telegraph. If a lecture is announced to be delivered on telegraphy, as was the case at Exeter a short time ago, we generally find large audiences. If a soirée is held, and any appurtenances of the telegraph are exhibited, they are sure to attract attention. This growing interest in the subject should be encouraged; and if private firms will not go to the expense of affording the public information, our flourishing companies might forward a few instruments, &c., to any place where the dissemination of knowledge is likely to prove useful in bringing the telegraph into more general use.

We wish the New Zealand project every success, and hope that if our manufacturers are indifferent to this appeal some of the large corporate bodies will give a favourable consideration to our suggestion, and that telegraphy will be well represented at Dunedin in 1865, as it is "eminently calculated to aid in the development of the colony."

THE ELECTRO-MAGNETIC PHONOGRAPH.

By J. Beverley Fenby.

So keenly have musicians at all times felt the extreme tediousness of writing music by hand, and the impossibility of preserving the most valuable impromptu pieces in their full and flowing beauty, that immediately on the introduction of the pianoforte into England, strenuous efforts were made by men of inventive skill to supply the instrument with the means of registering the music performed upon it.

"The first pianoforte seen in England was made by one Father Wood, an English monk at Rome, and by him sold to Samuel Crisp, Esq., who sold it again to Fulke Greville, Esq., for one hundred guineas."—*Rimbault's History of the Pianoforte.*

This was about 1757.

The Rev. — Creed would appear to have been one of the first, if not the first, to think of constructing a melographic piano or harpsichord, and in the year 1747 he sent to the Society of Arts a paper, entitled "A demonstration of the possibility of making a machine that will write extempore voluntaries, or other pieces of music, &c." —*Phil. Trans.*, vol. xliv. p. 445.

There are also obscure accounts of a machine made in 1770 by a monk named Engramelle.

In a German work of 1774, John Frederick Unger, a counsellor of justice at Berlin, claims priority of invention against Mr. Creed, though it seems most probable that each made a similar invention unknown to the other.

There is no doubt whatever that the Académie of Berlin was presented by Hohlfield—an ingenious mechanic who received some suggestions from Euler—with a machine which, to a limited extent, answered its purpose. It consisted of two cylinders moving paper between them, on which, by means of a crayon, each key made a mark when pressed down in the act of playing. But not only was the action of playing very fatiguing, but the music must have been of a most inconvenient width—that of the key-board—and without any stave, accidentals, &c.; in fact, a mere series of dots showing such and such keys were pressed down in the course of the performance, but utterly failing to mark the time, key, or accidentals. The Académie, however, in consideration of the great ingenuity of the contrivance, rewarded the inventor with a handsome gratuity.

"In 1827 M. Carreyre made trial, before the Committee of the Fine Arts of the Institute of France, of a *melographic piano*, which consisted of a clockwork movement, which unwound from one cylinder to another a thin plate of lead, on which were impressed, by the action of the keys of the instrument, certain peculiar signs, which might be translated into the ordinary notation by means of an explanatory table.

"After the experiment the plate of lead was removed to make the translation, and a commission was appointed to report; but as no report was ever made, it is probable that the translation was not found to be exact. At the same time M. Baudouin read before the institute a paper, accompanying it with drawings, concerning another melographic piano, upon the merit of which we do not find that the institute pronounced."—*Rimbault.*

These accounts prove two important facts: the great efforts made and the small success achieved—this want of success proceeding from the lack of a proper motive power, none having used electro-magnetism—for it must be evident to all acquainted with music that these were as yet nothing more than partially successful experiments, and produced no further results than stimulating inventors to continued exertions.

The causes of failure were many, the most serious being the oversight of endeavouring to derive the mechanical power from the keys of the piano, whereas some power—which, while depending upon the action of the key for its liberation and manifestation, should, at the same time, exert its force without strain upon the key—still remained a desideratum. Such a power is electro-magnetism, as the mere motion of a piano-key—without any alteration in the touch required—may be made to call forth a force of any magnitude, from ounces to tons. Now, in Unger's machine the power was derived from the keys alone, and by direct action, thus rendering the touch of the piano so heavy, that no one could perform properly upon it. For this reason it is unnecessary to consider further its defects. M. Carreyre's, besides being equally objectionable on the score of its unavoidably heavy touch, and arbitrary and unmeaning signs, produced at the best but an indented sheet of lead, a medium for writing music on most inconvenient and unmanageable.

A machine which should register in plain black and white on common paper the music performed, giving the score on the ordinary stave, using the flat, sharp, and natural signs, as in all modern music, accurately registering time, bars, legato and staccato, 8va, alta, and bassa passages, and adapted to all keys, still remained a desideratum, for from 1827 to 1863 no further progress was made, though many continued to give their attention to the subject.

But in 1863 electro-magnetism was applied, and the required conditions were all fulfilled, for a machine was patented January 13th, 1863, which, without altering the touch or appearance of an ordinary piano, is yet capable of registering the most complicated music.

Before giving any detailed description of the construction and capabilities of the phonograph, it may be well to make a succinct analysis of the obstacles to be overcome in the notation, and thus to separate the possible from the impossible.

The most obvious difficulty—and one which, if not overcome, would render all other excellencies nearly, if not quite futile—is the means of marking the various durations of the notes, from the breve to the demisemiquaver, &c. This was a difficulty, inasmuch as the ordinary open, closed, and tailed notes cannot possibly be rendered available in an instrument registering that which is performed upon it.

The following considerations will render this apparent. The longest note is practically but the fusion of a number of shorter notes, from which it follows that on any particular key being depressed, as in playing, its first touch would be the shortest note of the notation, and the machine would immediately print such shortest note, and could not afterwards alter it; for to suppose a piece of machinery to render shorter or longer notes by arbitrary signs, having but a fictitious relation to their duration, is to suppose its possession of a reasoning power, the absurdity of which needs no comment. From these considerations, and others which will readily occur to the mind of the reader, it is manifest that some system is required in which the duration of sound and the performance of the printing may be co-existent, and thus produce a complete reciprocity of action between the two. In other words, a short note must be capable of becoming a long one in the printing as in the playing. This is shown in the phonograph by the length it occupies in the bar.

Having considered the notation, the next thing to which our attention will naturally turn is the mechanical appliances employed to produce this notation. First, then, as to the touch of the piano; this remains, to all intents and purposes, the same as if without the phonograph attached, as the mechanical power is not derived from the motion of the keys, but from a voltaic battery: the only part performed by the key being to bring a small brass stud, on its under side, in contact with a slender spring; this causes an electro-magnet to slide a tracer against the paper, which is continually moving at a fixed rate, and thus marking the note. When the key is no longer depressed the tracing ceases, and the rod slides back; this mechanism being capable of registering the slowest or most rapid playing. The accidentals are printed by revolving type, acted on by the same sliding-rod and magnet. The accidentals are adapted for all keys, so that any number of flats or sharps may be correctly registered; the machine being capable of distinguishing *accidental* flats, sharps, and naturals from those which are proper to the key in which the music may be pitched. That is to say, if the key of A natural be used, F, C, and G, when played sharp, will have no sharp sign in the body of the music; whereas, if the naturals of these notes be struck, or the sharps of any others, suitable accidentals will be printed.

As we have now reviewed the notes and signs proper to them, we will next take the bars. The barring of the music is performed in such a simple manner as precludes the possibility of derangement, and is yet so accurate in adjustment, that it correctly follows the accentuation of the most complicated piece of music. When a rallentando movement occurs, the bar or bars through which it runs will be actually lengthened in such a proportion as will accurately denote the character and expression of that part of the music. The same manifest advantages occur in the matter of legato and staccato movements.

The machine requires only blank paper, as it rules the stave and prints the score simultaneously.

As to many the use of a voltaic battery may *appear* puzzling, the following remarks may not be out of place. In the first place, there is nothing of danger or inconvenience in the battery furnished with the phonograph, as no acid or other corrosive substance is used. The charge consists of sulphate of copper—commonly known by the names Roman or blue vitriol—and water, one charge lasting for some months. The whole is in a neat drawer at the bottom of the machine, and offers nothing of difficulty or unpleasantness in its management, and requiring to be touched only to supply water to it.

Substitutes for Gutta-Percha.—Sir W. Holmes has forwarded to the Council of the Society of Arts, from Demerara, some specimens of a gum termed "Balata," the produce of the Bullet tree (*Sapota Mulleri*), which grows in that colony, and which, he states, possesses the properties of gutta-percha, and may be used as a substitute for it. The specimens include not only the inspissated juice, but also a bottle of the juice itself. Mr. Ondaatjie, colonial surgeon, has forwarded to the Council, from Ceylon, a specimen of the *Alstonia Scholaris*, which he states may be used as a substitute for gutta-percha. It is stated to possess the same properties, and is as workable as the latter. It readily softens when plunged in boiling water; is soluble in turpentine and chloroform; receives and retains impressions permanently, and is adapted for seals to documents. The tree abounds with milky juice, like the gutta-percha, has a fleshy bark and porous wood, and belongs to the natural order, Apocynea. The natives believe that the tree is very poisonous, and class it among their virulent poisons, but Mr. Ondaatjie states that his experiments with the juice, &c., have proved the contrary. These specimens are sent in response to premiums offered by the Society of Arts for the discovery of a substitute for gutta-percha.

THE INTERNATIONAL EXHIBITION, 1862.

(Continued from page 101.)

4. *Relays, or Intermediate Instruments by which Signals, when received, are retransmitted through a Second Circuit.*

Signals sent through long circuits are now very generally received in the first instance by *relays*, or instruments designed to retransmit the signals into a fresh circuit, from a local battery. The second circuit may either be a second line, or simply a local circuit, including a recording or other instrument, which could not be worked directly by the feeble currents received from a distance.

Relays were not generally used in this country or on the Continent in 1851, although described by Professor Wheatstone in connection with his early inventions; they came first into general use in America, and have since then been very extensively introduced in connection with Morse embossing instruments; they are now being to some extent abandoned in favour of the direct ink-writing Morse instruments, of which specimens are exhibited by Messrs. Digney and Messrs. Siemens.

A good relay should be easily adjusted so as to work with any required strength of positive or negative currents. It should work freely under the influence of an extremely small rise and fall of current above and below the strength of current to which it is set (this will, of course, be frequently zero when reverse currents are used), and when once adjusted to a given strength it should be constant—that is to say, should always work with the same rise and fall above and below the strength to which it is set. This condition of constancy is extremely difficult to fulfil when soft iron is used.

The moving parts should be very light, and traverse the shortest possible space, in order to allow of rapid work under the influence of small forces. Finally, the contacts should be so arranged as to be easily adjusted and cleaned.

The relays exhibited by the French makers are of the simplest possible construction. A soft iron hollow cylindrical armature on one end of a rocking lever is attracted downwards by the two poles of an upright horseshoe electro-magnet during the passage of a current. An antagonistic spiral spring lifts the armature again, when the current ceases. This spring can be adjusted by a screw; the contacts required are on the rocking lever. These relays are only intended for rough work; the weight and consequent inertia of the moving parts is so great, that they cannot be worked at any speed with weak currents; moreover, the residual magnetism and coercive force of the large masses of soft iron render any delicacy of adjustment impossible, as will be more fully explained when treating of Messrs. Siemens' relays.

Digney Brothers & Co., Paris, M. (France, 1,414), exhibit an instrument (systême Melloni) in which the movable armature is so shaped as to receive a coil supplementary to that of the main electro-magnet. The received current circulates round this armature in such a direction as to give its ends an opposite polarity to that of the poles of the main electro-magnet facing them. This arrangement does not remove the difficulties arising either from inertia or from residual magnetism, although it must increase the force exerted between the fixed electro-magnet and its armature with a given current, and a given amount of resistance in the coils.

M. Hipp, Neufchâtel, M. (Switzerland, 156), exhibits a good and cheap relay similar in general appearance to the French relay. The peculiarity of this instrument consists in the application to the armature of two antagonistic spiral springs intended to produce greater liveliness or rapidity of motion than can be obtained under the action of gravity alone. The armature is light, and rocks on knife edges.

Siemens & Halske, M., Berlin (Prussia, 1,413), exhibit a *polarized relay*, possessing an electro-magnetic arrangement of great merit, which has also been largely used for direct receiving instruments. The soft iron cores of two straight electro-magnets are joined by a back so as to form the usual horseshoe electro-magnet; this back rests against one pole of a powerful permanent steel magnet, which communicates its own—say north—polarity to both branches of the horseshoe. A tongue of soft iron is centred so that one end can oscillate between the ends of these two branches, and this tongue is supported by the opposite pole of the permanent steel magnet, which is bent into a convenient form for the purpose. This tongue, therefore, partakes of a polarity opposed to that of the branches, in virtue of which, when no current passes round the electro-magnets, it rests attracted indifferently to whichever of the two branches it may happen to be nearest. (This arrangement gives an example of what have been called the unstable receivers.) The effect of a current through the electro-magnetic coils is to weaken the polarity of one branch and strengthen that of the other, so as no longer to allow the tongue to remain indifferently in juxtaposition with either branch, but definitely to attract it to one side, at which side it will remain, until a current in the opposite direction round the coils produces an effect in the branches the reverse of that which last occurred.

By adjusting the relative distances between the two branches and the tongue, and by diminishing the play of this tongue to a small fraction of the total distance which separates them, very great sensibility can be obtained; and, moreover, the instrument, although specially designed to work with nearly equal reverse currents, can be set so as to work with positive or negative currents alone at any strength, as well as with reverse currents of any required relative strength. This plan possesses the advantage of allowing the current to act on highly-magnetized iron. No springs are used, and the position of the branches relatively to the tongue is regulated by a fine screw.

For many purposes this arrangement of receiving electro-magnet and armature is probably the best exhibited; but it possesses the one great defect inseparable from every arrangement in which soft iron plays a part. This defect may be described by saying that similar or equal currents do not produce similar or equal polarities in the soft iron at different times. For, owing to the residual magnetism, a negative signal occurring after a series of positive currents, or after a long positive current, does not produce the same effect on the soft iron as a negative signal occurring after a series of negative currents, or after a long negative current, and neither effect will be the same as that produced by the first few currents received after the soft iron has been for some time free from all electric influence.

This necessary consequence of the coercive force of soft iron frequently renders extreme delicacy of adjustment quite useless; for, although the relay may be set so as to work with an exceedingly small variation in the received current, the continual changes in the condition of the soft iron require to be followed by a continual readjustment undesirable in practice. This defect has led to the invention and use of the so-called *galvanometer relays*, in which the force obtained from the received current is far smaller than in the relays hitherto described, but is constant and always to be relied on.

In galvanometer relays the contacts are produced simply by the deflection of a hard steel magnetized needle under the influence of a coil or coils of wire, without the use of any soft iron whatever. So long as the currents used do not exceed a certain strength, their only sensible effect is to produce an alteration in the position of the needle. They leave its magnetism quite unaffected; and equal effects are therefore always produced by equal currents. These instruments once set require little or no adjustment so long as the condition of the batteries and the line remains sensibly constant.

C. F. Varley, M. (United Kingdom, 2,981), exhibits a simple galvanometer relay with rubbing contacts, much used by him, and found to work very well in practice.

The British and Irish Magnetic Telegraph Company, M. (United Kingdom, 2,864), exhibit another form of galvanometer relay, called the mercurial relay, and invented by Sir Charles Bright. The difficulty found in making good contacts with galvanometer relays, owing to the small force experienced by the needle, is here obviated by the use of mercury contacts, and the oxidation of the mercury is prevented by making these contacts between the needle and a fine stream of mercury constantly in motion. The same mercury is used over and over again, running from one reservoir to another like the sand in an ordinary hour-glass. The reservoirs are reversed when the upper one is empty. This instrument is specially mentioned in the award of a medal to the exhibitors.

This company also exhibits another form of relay, designed by Sir C. Bright, by which positive and negative currents are retransmitted into the second circuit in the order in which positive and negative signals are received. This instrument may be described as having two armatures worked from the opposite poles of two straight electro-magnets. One armature is set so as to work with positive signals, and used to connect the positive pole of a battery with the second circuit; the other set so as to work with negative signals, and used to connect the negative pole of a battery with the second circuit; the two straight electro-magnets stand side by side, and the two steel magnetized armatures are placed at the opposite

ends of the pair, centred on an axis between the two poles. This compact arrangement has been largely used for many years.

T. Allan, M. (United Kingdom, 2,850). The contact pieces of ordinary relays, as has been already observed, require frequently to be cleaned and readjusted, as they are more or less burnt or oxidized by the spark given from the local battery whenever the local circuit is broken.

Mr. Allan has, by a very ingenious arrangement, avoided this inconvenience, and exhibits a "sparkless relay," specially mentioned with approval in the award by which he has received a medal. The *name* "sparkless relay," nevertheless, is hardly correct, for this invention does not consist in the peculiar arrangement of the relay, but depends on the general system of code, relay, and recording instruments.

The code of signals used by Mr. Allan is formed, as already explained, by the grouping of a single line of dots, and a dot is recorded indifferently on the reception of a positive or negative current. His sending instrument reverses the current each time a dot is required, and maintains indifferently a positive or negative current for the space between two dots. The relay differs little except in the arrangement of its contacts from those usually employed, and its armature moves to and fro in the usual way under the alternate influence of the reversals received; but the circuits in connection with the two relay contacts are so arranged that, whether one or other contact is made, the recording instrument prints a dot, and, in the very act of doing so, breaks by a spring contact piece the local circuit which had just been completed by the relay. (The spring contact piece, moved by the clockwork of the recording instrument, also replaces a connection in a second local circuit which had been broken by the previous dot.) The spark caused by the interruption of the local circuit occurs, therefore, at the rough spring contact, where it is of no consequence, and the relay armature on moving to the opposite position when a fresh signal is sent, breaks no circuit and causes no spark. On arriving at the second position, it closes a second local circuit (containing the connection mentioned as replaced by the spring contact when the previous dot was received); this circuit prints a perfectly similar dot to that printed by the first circuit, and in so doing is broken by the spring contact piece, which replaces the connection broken in the first circuit when the first dot was received. Thus, there are two local circuits with two interruptions in each—one in the relay and the other in the printing mechanism. The function of the relay is to close these two local circuits, each of which prints a perfectly similar dot, while the printing mechanism alternately breaks and makes good the two local circuits at the second interruption; when it interrupts the circuit it stops the current, and the spark occurs, but when it makes good the previous interruption, it does not start the current, but only prepares the circuit for the next movement of the relay. The result and object of this cycle of events is to remove the breaks of the circuit from the delicate relay contacts to spring contacts, which, as they are moved by the powerful printing mechanism, can be so treated as to render the spark quite innocuous. Mr. Allan here uses strong rubbing contacts of platinum.

Mr. Allan employs this arrangement with his special automatic system, but it is clear that the same principles are perfectly applicable to any of the common forms of relay, and the Digney or Siemens writer, entailing only the addition of some obvious details.* It is, however, essential that the code or alphabet should be composed entirely of dots. One advantage of the sparkless system is, that the travel of the relay armature between its contacts can be reduced to a minimum, since this plan entirely obviates the well-known chattering or trembling effect produced by the passage of a succession of sparks in the usual relay when the travel is too much diminished. The system appears especially adapted for use with galvanometer relays.

The relay exhibited is composed of a light, hollow, steel magnet, the two poles of which oscillate between the four poles of two horseshoe electro-magnets. The adjustment is obtained by movable eccentric soft iron poles on these electro-magnets.

5. *Receiving Instruments, which show or record the Symbols of the Codes described.*

We now come to the instruments on which the signals are finally received, and either read by eye, by ear, or recorded on paper to be subsequently deciphered. The well-known *needle* instruments are simply various forms of galvanoscope, in which magnets, deflected under the influence of a coil of insulated wire, move an index needle, by means of which the number and order of the currents received are observed by the receiving clerk, who interprets their meaning. Needle instruments are generally used without the intervention of any relay or local battery, and are the simplest, but far from the worst, form of receiving instrument. Examples are shown by—

The British and Irish Magnetic Company, M. (United Kingdom, 2,864), and Messrs. Reid Brothers (United Kingdom, 2,940). They do not require first-rate workmanship, and the examples shown do not present much that is novel, but it is interesting to see how this simple and somewhat primitive instrument holds its ground against a multitude of contrivances of great merit and ingenuity.

The form of magnet in Highton's patent, shown by the British and Irish Magnetic Company, deserves remark. It is a horseshoe, bent from a rather broad steel plate, and centred on an axis, passing through the bend of the horseshoe between the two poles. The coils surrounding this magnet are circular, and lie in planes parallel to that containing the axis, and the line joining the two poles of the magnet. This form of magnet can be powerfully magnetized, retains its magnetism well, and all the moving parts are close to the axis of rotation.

The Morse recording instrument consists essentially of clockwork, by which a strip of paper is drawn forward at an uniform speed, and of an electro-magnet and armature, with which a marking point is mechanically connected. As the armature moves under the influence of the received current, it alternately presses this marking point against the paper, and withdraws it, leaving a series of slightly embossed marks of greater or less length, corresponding to the duration of the received currents; the clockwork is driven by weights, or by a barrel spring, and the speed is regulated by a fly. It is difficult to conceive a simpler recording instrument, and its general adoption on the Continent is, doubtless, due to its simplicity. In order to produce distinct impressions on the paper, the armature must be moved with considerable force, and the instrument is, therefore, in this form almost invariably worked by a relay in connection with a local battery and circuit. This primitive instrument will, however, apparently soon be superseded by improved forms, in which the embossed marks are replaced by ink lines, which can be printed with little pressure, so as in general to dispense with the relay and local circuit.

M. Hipp, Neufchâtel, M. (Switzerland, 156), exhibits a Morse receiver of good practical construction; all the wheelwork and the electro-magnets are under cover in a case, of which the top is plate-glass; the bearings for the pivots are also covered, so that all the moving parts are completely protected against dust. Moreover, the paper roll, the adjustment, the stopping and starting handles, the guide, &c., are conveniently placed. There are more than 1,000 instruments of this kind at work in Switzerland and Italy. It is said that they work a very long time without requiring to be cleaned or repaired. Considering the workmanship, the price—£8 8s.—is very moderate.

T. Sortais, Lisieux, H. M. (France, 1,447), exhibits a self-starting and stopping Morse receiver. In the usual form the paper must be started when a call is heard, and stopped when the message ends. M. Sortais throws these functions on the apparatus itself. The train of wheels is driven by a weight or spring in the usual way, and stopped by a catch, which comes in contact with the fly used to regulate the speed. This catch is a long counterpoised lever centred on an axis, which also carries a ratchet-wheel. The counterpoise tends to turn the ratchet-wheel and lever so as always to free the fly; this motion is restrained by a paul, which arrests the ratchet-wheel. When a current is received, the writing lever moves in the usual way, and lifts this paul out of gear with the ratchet-wheel. The counterpoise falls, turning the ratchet-wheel and releasing the fly; the train of wheels then starts, and draws the paper forward. A projecting tooth on the axis of one of the pinions of the train catches against the teeth of the ratchet, and at every revolution turns it one tooth back, lifting the counterpoise, and bringing the catch nearer to the fly. If the paul is down, each tooth so gained is kept, but if currents continually arrive, lifting the paul, the counterpoise continually falls back to its lowest position, and the clockwork continues in motion. When the message ceases, and the writing lever remains still, the paul keeps each tooth of the ratchet-wheel lifted by the projecting tooth on the pinion axis, until after some revolutions the ratchet is turned

* Mr. Allan differs from the writer here, and says that his arrangement cannot be applied with advantage to the common receivers.

so far round as to bring the catch against the fly, thereby stopping the clockwork. The relative position of the fly, catch, and projecting tooth are so arranged that, when the fly is caught, the projecting tooth is necessarily clear of the ratchet-wheel, which is therefore free to turn the moment the paul is withdrawn. M. Sortais requires no auxiliary electro-magnets, such as are used for the same purpose in an instrument shown by Messrs. Siemens.

The Imperial Telegraph Board of Vienna (Austria, 667) exhibit a Morse instrument, in which they use a little electromotor to drive the clockwork, instead of a spring or weights. This electromotor is automatic, that is to say, it is started by the arrival of the first signal, and stops some time after the last. This is effected very simply. The first movement of the writing lever caused by the arrival of a call or message, lifts a lever off a catch, the lever then falls on to a cam on the axis of one of the train of wheels. The contact between the cam and lever completes the local circuit, and starts the electromotor. Once during each revolution of the cam, it brings the lever into such a position that, if no signal were then received, it would fall on to the catch, and *shortly afterwards* the cam would quit the lever and break the local circuit. This instrument is ingeniously combined and well made, but it will probably for the present be found better in practice to depend on weights or springs for the driving power.

A second Morse embossing receiver, exhibited by M. Hipp (Switzerland, 156), would be of much greater interest were it not for the successful ink-writers exhibited by Messrs. Digney and Siemens. M. Hipp has ingeniously contrived to obtain the force required to emboss the paper from the driving power of his clockwork, using the receiving electro-magnet only as it were to throw the driving power in and out of gear. M. Hipp intended by this means to dispense with the relay, but the "ink-writers" will probably prevent any extended use of his instrument.

Digney Brothers, Paris, M. (France, 1,414), exhibit a receiving instrument, by which the Morse signals are marked in ink on the paper strip. The arrangement of the armature and receiving electro-magnets is similar to that used in Messrs. Siemens' polarised relay: an arrangement which, as already explained, allows the instrument to be worked equally by voltaic or magneto-electric currents. When a current is received, a light lever connected with the armature of the electro-magnet lifts the paper strip, and presses it against a small disc, called the writing disc. When the current ceases, the paper is allowed to fall clear of the disc. This disc is kept in continued rotation by the clockwork, and turns in the opposite direction to that in which it would be driven by the paper when pressing against it. Its edge is kept moist with ink by a saturated felt-roller, which rests on its upper edge. The paper, when lifted against the disc, makes a slight angle at the point where it touches the disc, so as to be in contact with it for a very short distance only. The length of line printed depends on the time during which the paper remains pressed against the disc, just as in the old form the length of mark depended on the time during which the point was pressing against the paper. A very weak current gives sufficient force to lift the light strip of paper, and press it against the disc firmly enough to receive a good impression, and consequently the relay and local circuit, used with the old embossing instrument, can be dispensed with in most cases.

This useful instrument seems to be a sound practical improvement on the old form; it substitutes direct for indirect action, a distinct for an indistinct record, and, at the same time, saves battery power. It is now used to the exclusion of all other forms by the French Administration. The invention of the first successful ink-writer of this kind is generally ascribed to Mr. Thomas John, a Hungarian.

The particular manner in which the disc of these instruments receives the ink, admits obviously of many variations, and may probably be from time to time considerably improved. The original form—that of a moistened felt-roller—has several defects; the roller has frequently to be changed, and is apt at one time to be too wet, and at other times too dry, and, if unskilfully managed, soils the paper and the clerk's hands.

Siemens, Halske, & Co., M. (United Kingdom, 2,959), exhibit two modifications, one in which a little bottle has a porous stopper resting on the disc, and a second which seems greatly superior, having the disc half immersed in a trough of ink, which is kept at a constant level by tilting more or less a large reservoir. An adjusting screw enables this to be done gradually and accurately. The little disc as it revolves in this trough is always equally wet, and the operation of refilling the reservoir need not cause either dirt or delay. In this arrangement the armature moves the disc up against the paper, instead of lifting the paper up to the disc. The disc receives its independent motion of rotation through a double swivel joint at the end of a long axis.

The point of chief importance is the independent rotation of the disc in the direction opposite to that which the contact with the paper would produce; and this peculiarity is common to all the forms hitherto mentioned. It is this rotation which in all these forms keeps the edge in a constant, or nearly constant condition, both during the transmission of signals, and during any pause or interruption.

Messrs. Digney, M. (France, 1,414), exhibit another modification of the Morse instrument, in which, instead of the polarized Siemens electro-magnet, the armature is arranged as in the relay already described, under the name of Système Melloni. In one of Messrs. Digney's instruments the coils round the relay are subdivided, and can be used in series or multiple arcs, so as to be adapted for shorter or longer circuits by the alteration of its resistance.

E. Tyer (United Kingdom, 2,977) shows two Morse ink-writers. In one the ink is supplied to a little nipple on a tube over the paper from a reservoir above it, flowing through the tube past the nipple, and down into a second reservoir. The paper is marked when pressed up against this nipple, but the hole in the nipple is too small to let the ink run out, except when the paper is pressed against it; the constant current flowing past the nipple keeps it from clogging. When the upper reservoir is empty, the two reservoirs are turned round, a fresh nipple is presented to the paper, and the ink flows back into the first reservoir.

The second ink-writer has a disc supplied with ink from a saturated cloth, which never leaves the disc, and therefore keeps it always moist; the disc has not the independent motion of rotation which is, in the writer's opinion, necessary to keep all points of its surface equally inked at all times.

M. Hipp, M. (Switzerland, 156), exhibits a telegraph receiver of novel construction, designed with a view to obtain increased speed of signalling with less battery power, and without the use of relays. He proposes to use what we have called the Steinheil alphabet, recorded on a slip of paper by two rows of embossed dots.

The peculiarity of the instrument consists in the fact that the strength of the electric current has no influence whatever on the force or rapidity with which signals are printed. The current received releases one of two armatures, the attraction of which to their respective electro-magnets is almost exactly balanced by adjustable springs. One armature is freed by a positive, the other by a negative signal; their movement releases a catch, whereupon the clockwork prints the required dot, and replaces the armature with extreme rapidity. The key for the operator is arranged as in a pianoforte, and a letter is sent by depressing a certain number of keys at once, as in playing a chord.

There can be no doubt that the arrangement of the receiver will allow great rapidity and force of action to be combined with excessive delicacy. The limit of the delicacy of adjustment is determined by the variation in the residual magnetism left after a succession of positive or negative signals respectively. M. Hipp considers that 180 letters can be sent by hand with this instrument, and there seems no reason to doubt this, judging by the performance of the clerks with Sir Charles Bright's acoustic telegraph.

(To be continued.)

ELECTRIC AND COSMICAL.

WE extract the following interesting observations from the *Weather Book* of Admiral Fitzroy, F.R.S., with the view of affording our readers an opportunity of discussing the questions raised:—

Electricians are familiar with "*circuits*"—completed circuits; and will probably think a person who asserts that *a circuit may be fallacious*, only proves his utter ignorance of the subject.

Undeterred, however, by this probability, the author attempts now to show that such theories are insufficiently supported by facts, and that the effect called "completion of a circuit" is caused in a manner altogether different, and hitherto unexplained. It is well known that communication existed for a short time between Valentia and St. John's, in Newfoundland, *under* the ocean, through a wire, or combination of wires, some 2,000 miles long; and very lately telegraphic messages were sent from London to Corfu, also

about 2,000 miles, in less than two seconds. In both cases the accounts allude, or rather refer explicitly, to the *return currents* of electricity—supposed to traverse the earth, through land and under sea, from one extremity of each great distance direct to the other—to "complete the circuits."*

To suppose that electricity darts from one point to another, immensely distant, rather than to any other much nearer recipient, at least *equally ready* to receive it, is a strain on imagination not easy to be borne.

The writer of these words has never been able to believe that such is the case, and now will offer a few considerations.

1. He has thought that electricity may be an etherial *influence*—not tangible or ponderable like any material fluid.

2. That space may be filled with such an influential ether, *infinitely elastic* and self-repellent.

3. That dry air is almost a non-conductor of its action.

4. And that *our* earth may be a vast reservoir, abounding in electricity—always ready to receive from space, while equally so to communicate to any point on earth's surface which may be less electrified than earth itself, and connected with it by a conductor.

5. Electric influence (or ether) may be cold, proportionately to its less resisted *expanse in space*.

6. Heat may be caused by compression of electricity (etheric influence), or by resistance to its expansion.

7. Matter in space, *acted on from every direction* by infinitely compressing *influence*, may become concentrated and heated, then develope a non-conducting atmosphere, and may acquire rotation in consequence of alternations and oppositions of electric influence within and without such an atmosphere, caused by heat acting against cold.

8. Under such conditions, any communication through *air*, by a *conductor*, upward or downward, from earth or from above, would facilitate electric action, which is invariably from the more electrified or influenced matter—to the less influenced—or, as *usually* said, from positively electrified to negatively electrified; the *direction* of action being unimportant, *supposing that one influence only* exists, which pervades all space, and is latent in all matter, in greater or less degree.

To go now into *reasons* for these suppositions—strange, even absurd, as they may appear to some persons unacquainted with Higgins's views,† with Faraday's expressions about gravitation, and with Newton's questions as to the real nature of gravity—would be unadvisable. The author ventures to write them here only to show why he believes that effects of the commonly received "circuits" of electricity may be more naturally and intelligibly explained in the following manner.

Whenever an electric effect (*usually called a current*) is to be caused through a conductor, *influence* must be generated, and accumulated by a battery, coil, or machine; and near each end of the conductor, however long or short, a wire must be "*put to earth*." The popular idea is that a current flies through the conductor, and returns through the earth. But the real effect, it is here submitted, is that earth *receives* influence sent along a conductor, and at the *same* time imparts equivalent influence to the battery end of the conductor, without which distinct and unconnected actions there could be no more transmission of electric influence along a wire than there could be of water along a pipe of which the farther end were closed, and a *vacuum* caused by any motion of fluid from the nearer end.

Imagine 10,000 inelastic, say adamant balls touching each other in a very long inflexible tube, *just* containing them in one direct line. Suppose the nearest struck sharply, all would feel and move, but *only the farthest* would drop out—though not even then, if a *vacuum* would be caused by displacing the *nearest ball*. The popular idea of flight, as it were, of electricity—fluid or something else—from one end of a conducting wire to the other, has usually been inseparable from the thought that *particles* actually traversed the whole length, however long, through or along the metal, instead of exactly considering and fully appreciating the action of a *conductor*, through air (a non-conducting medium) or in water if sufficiently insulated—by which an electric influence can be *connected or projected*—as action of a magnet on iron filings can be conveyed through an indefinitely long wire, though that magnet would not affect them, through air only, at a few inches distance.

But the author does not deny the *appearance* of circuits caused by closing, or approximating the ends of *any* conductor, *however long*, which are actually brought near, or to touch each other. He only ventures to deny the *transfer of particles* from sender to receiver—*as in the other case*.

Electric influence seems to act similarly to its correlatives, magnetic attraction and repulsion, which afford the least complex illustration of such a mysterious power acting in *lines of force*.* And where non-conducting air is *absent—as in space* beyond our atmosphere—who can say how far such influential forces may be always operating on our world—and, if so, on the universe.

Pervading all *space*—permeating all aeriform, gaseous, liquid and solid bodies—an *influence* seems to exist, ambiguously mentioned, rather than explained or defined, by the term Electricity.

Between this influence and caloric, and ether, and light, and magnetism, so close are the connections or correlations, and so indefinite are any even imaginary limits, that no man now can discriminate accurately where one merges in the other, or prove to demonstration whether each such apparent or sensible, though imponderable element, may not be but a condition or modification of *one etheric principle*.

Facts seem to indicate that such a principle (for brevity here called *etheric* and referred to by the familiar term ether) must be very elastic and *self-repellent*, but attracted by matter to a certain degree—namely, the point of saturation.

Cold when expansive, hot when compressed, its cosmical tendency would seem to be concentration of ponderable matter, development thence of heat and generation of atmosphere.

Earth's aeriform envelope, *almost* saturated with (the *influence* here called) ether, may be *slow* to receive *more*, or to part with any; therefore, with respect to *infinite* space, and to our relatively central earth, may be considered as nearly non-conducting—in fact, a very slow dielectric.

If all matter retains a certain quantity of *latent ether* (rather than caloric), pressure, compression, friction, impact, or contact, may cause augmentation of sensible heat, proportionate to force or duration, or both together.

Conversely—inaction, expansion, evaporation, or radiation, may cause cold, in proportion to their degrees.

Ether, from or in space, may be cold. That in earth, heated by compression and *considerably* more expansive or elastic, may always *tend* to escape, but is enclosed by our atmosphere. Hence the readiness of *earth ether* (*excessive* electricity) to replace any void in air (caused by voltaic or other electric agency), and the constant necessity of such an *extra force*, to impel a so-called current along a wire *into* the earth beyond.

The heated ether of earth may have been *known* by the terms negative, resinous, or minus electricity—although such words seem now to indicate one and the same state or condition of a principle, or influence, that varies in equilibrated tension according to circumstances—certain temperatures, states of matter, and *relative* expansion or compression.

Atmospheric currents seem to be electrified (or *etherised?*) *differently*, when proceeding *from* the torrid zone, as compared with their state while coming from a pole. And their inter-action, or friction, in crossing, *super-passing*, or otherwise affecting each other, may cause electro-magnetic "*earth-currents*," or telegraphic "wire disturbances," notwithstanding that such phenomena are found to occur rather before any considerable changes of air-currents (winds), whether from tropical to polar, or the contrary, are noticed. These changes are not necessarily violent; on the contrary, they are sometimes so gradual as to be scarcely remarked by general observers; but no important change or alteration of wind happens (as far as the writer is yet aware) without some of these remarkable supposed indications of such aerial collisions.

Auroras and "*magnetic storms*"—or disturbances of magnets at observatories †—have been noticed as synchronous with earth currents along telegraphic lines; and it is, at all events, a popular belief that strong winds usually follow auroras.

In Great Britain the action of a polar current is shown by "deflections," and other disturbances, chiefly along the wires that run eastward, and to the north, from London. Deflections on the western and southern lines (*from* London) *seem*, as yet, to indicate appulse of a tropical air current—principally.

Deflections (so called), on all lines, show general disturbance of the atmosphere, by collision of currents, and are premonitory.

---

* Such a length—or the *interval* between *any* two stations—may be well termed a *span*?

† Comparative View, Second Edition, 1791; and his Atomic Theory.

* Faraday.

† C. V. Walker, and Balfour Stewart, F.R.S., in Phil. Trans., 1861 and 1862.

These occasional, but apparently *periodic* effects, seem to be closely correlated to those aerial overflowings in the torrid zone which have been described in the eighteenth chapter of this book.

Suppose that *continuous* streams are caused from upper tropical regions toward each pole (as there expressed), and with return currents from the poles, such horizontal and derivative motions would increase, decrease, or vary, like tidal *currents* occasioned by great tidal elevations or depressions. "A continued stream may be produced by a succession of impulses, as a rotary system of waves may be kept in constant circulation by impulses received from the adjacent tides."*

If these views are based truly, and are legitimate inductions from facts, *Solar action* may be shown to vary in its *effects*, during a certain number of years, in addition to those ordinary consequences of annual changes exemplified in seasons.

May not *decennial*, or other variations of solar causation,† be traced indirectly, if not, indeed, directly, by prolonged observations of these mysterious currents—already referred by some philosophers to *temperature* within the earth,‡ or, by others, to the direct action of our great luminary?

Seeing that impulsion, or forcibly sudden impact, causes heat, if not also fire, may not *prolonged* compression induce slow combustion, as effect of ether and oxygen?

Polar currents of *cold* air, much etherised, may have an excess of plus, vitreous, or positive electricity, Tropical (*warm*) ones may be minus or negatively electrified? Or conversely?

In regions where *extreme* atmospheric qualities approach, or meet—as in or near the tropics, where air and water are much heated—while *space above* remains cold, and where mountains reach to a climate cold even in summer, lightning and thunder-storms are very frequent.

On the other hand, in the icy high latitudes of polar regions very seldom is thunder heard, and rarely is lightning seen.

But the aurora is *very* frequent, and at times has *seemed* to be near, even close,§ as if within a few miles.

May not auroral exhibitions, so beautiful, and occasionally so *extensive*, *though synchronous*, be caused by *inter-crossing* currents of air that develope electric (or etheric) light in our atmosphere, chiefly where it approaches space, is incessantly whirled round as earth rotates, and is separated, while confined, at its *cold* outer limit?

What an electrician can effect in a room, by a machine and exhausted receiver, may surely take place, on an immeasurably greater scale, in atmosphere, or in the *comparative* vacuum near its outer limits.

Cold air, in polar regions, having much ether (or electricity), any friction, of inter-crossing air currents or otherwise, may cause its ready development.

Are not the working of an electric apparatus, rubbing a cat's back, combing hair, or even the harshness of one's skin, familiar evidences of a state of air extremely different from that which accompanies a tropical current of wind.

Ozone is prevalent with tropical winds, especially near the sea; but it is not so with polar wind, unless a temporary and merely *returning* current of tropical air.

"Northern Lights," "Merry Dancers," "Streamers" of various bright colours, at times almost blood red—illuminate the polar regions, are sometimes seen in the middle latitudes, and, though rarely, near the tropics.

Cold—excess of ether or electricity, dry air, and an upper, or *commencing* contest of aerial currents, seem to be invariably present when aurora is conspicuous.

The magnetic influence of ether (in electro-magnetism) is extremely remarkable—so little need there be of a merely *material* connection between a magnet in air, and iron or steel which it affects. That magnetic (electric or *etheric*) influence is not stopped, or entirely cut off, by glass, is shown by the action of a magnet on the steel index of a Sixe's self-registering thermometer; or by a compass needle, entirely surrounded by a hollow glass sphere—and in other experiments.

The attraction existing between electric ether and iron seems to be felt *similarly* to that of our earth and ether in space, although in an immeasurably less degree. In each case, as supposed above, a dielectric, already saturated with ether in a latent state, is interposed—whether glass, or the atmosphere.

Imponderable electricity, or ether, has had its *effects* weighed by a delicate balance* and its velocity measured† mathematically as well as practically.‡ Apparently diffused everywhere in and through every kind of material, perhaps throughout all space—surrounding closely and actually separating molecules,§ if not atoms, even *ultimate particles* of matter—it may be admitted to be the *principal agency* that is traceable in all our mundane if not in all cosmical operations.

Nevertheless, it is unquestionably a mere instrumental means. It has not been proved to affect anything except by such ordained laws as can be partly traced by man. It does not act till forced by some change of condition—of temperature—or of equilibrium:—and, for our beneficial use, it is sufficiently within human control.

REPORT OF THE TELEGRAPH CLERKS' PROVIDENT FUND.

THE Committee have much pleasure in submitting their Balance Sheet for the information of the members of the Telegraph Clerks' Provident Fund. Considering the short time that has elapsed since its formation, the progress and position of the fund must be considered most encouraging and satisfactory. The liberal donations which have been received, chiefly from those more or less connected with Telegraphy, and their consequent interest in the welfare of those who are dependent on that service, have enabled the Committee to invest £184. 2*s.* in the purchase of £3. per cent. consols to the value of £200; thereby forming within a few months a solid, and, it may be hoped, accumulative foundation for the future stability of the fund.

The annual subscriptions already promised, independently of sums to be received from members, amount to £55. 12*s.* 6*d.*, the greater portion of which have been received and invested as above.

The only liability beyond the current claims of members, is for the Stationery Account, Books of Rules, &c., the chief portion of which goods are still in hand, and available for the future working of the fund. It will be seen that the cash at the Bankers is more than sufficient to meet this liability.

It might have been reasonably expected that the establishment of the fund would be a work of time, considering that those for whose benefit it has been introduced are scattered over all parts of the kingdom, and possibly have not previously considered the general benefits of belonging to such a society. The Committee have, therefore, much satisfaction in stating, that although the fund has only been in actual operation since October last, it now numbers seventy-one members, composed of clerks and employés in the service of the Electric and International, the Magnetic, the United Kingdom, and the London District Telegraph Companies.

Several applications have also been received for information, Books of Rules, &c.

It should, however, be borne in mind, that the earlier members join, the greater permanent advantages they get by a reduced rate of subscription.

The Committee are glad to be able to report, that up to the present time the claims have been limited to two, and these are on the Sick Fund.

They also think it right to state, that Dr. Sutro, of Finsbury-square, has kindly consented to act as Honorary Physician; and that, through his introduction, Messrs. Baumgarten, of No. 520, New Oxford-street, and No. 113, Leadenhall-street, have undertaken to prepare his prescriptions for any members of the fund at cost price.

The Directors of the London District Telegraph Company have also kindly granted the necessary office accommodation for conducting the business of the fund gratuitously.

In conclusion, the Committee believe that they can safely report, that there is every prospect of the society assuming the position for which it was originally intended—viz., a Provident Fund for the present and future benefit of those in the employ of any Telegraph Company.

REPORT OF THE DIRECTORS OF THE SUBMARINE TELEGRAPH COMPANY.

THE annexed account for the half-year ending 31st December last, exhibit a satisfactory and steady increase in the Company's revenue.

The receipts for the past half-year, derived from 185,380 messages, amount to 25,184*l.* 1*s.* 2½*d.*; for the half-year ending 30th June, 1863, from 160,404 messages, 22,144*l.* 2*s.* 8½*d.*; and for the half-year ending 31st December, 1862, from 172,881 messages, 23,427*l.* 5*s.* 6½*d.*; while the ordinary working expenses remain nearly the same.

Since the last meeting of shareholders a considerable reduction has been made by the different administrations in Germany in their internal tariff, which, it is expected, will cause a still further increase in the traffic.

Owing to the prevalence of the unusually tempestuous weather during the autumn of last year, several of the cables suffered, unfortunately, considerable damage, and have burdened the revenue with a much larger expenditure than usual for repairs. Notwithstanding, however, this additional outlay, the Directors are enabled to recommend a dividend, at the rate of 4 per cent. per annum, although the capital has been largely increased by the issue of the new stock; to add the sum of 2,518*l.* 8*s.* 2*d.*, being 10 per cent. on the receipts, to the reserve fund (which will then amount to 6,441*l.* 7*s.* 0*d.*); and to carry over 774*l.* 13*s.* 9½*d.* to the next account.

It is with great regret the Directors have to announce the death of their lamented colleague, Mr. John Watkins Brett, who was one of the originators of this undertaking and to whose labours the world is mainly indebted for all the benefits arising from the establishment of the Submarine Telegraph.

Two gentlemen of much experience in the management of Submarine Telegraph Companies have declared themselves candidates for the office of Directors; one of them, the Right Honourable James Stuart Wortley, is the Chairman of the Atlantic Telegraph Company, and the other, Henry Moor, Esq., M.P., Chairman of the Mediterranean Extension Telegraph Company, and the Directors would, therefore, be glad to have their valuable co-operation at the Board.

In conclusion, the Directors have to mention the resignation of Mr. Courtenay, after twelve years' service as secretary, in consequence of his accepting an appointment under Government, in connection with the Indo-European Telegraph. It is with much pleasure that the Directors can bear testimony to the zeal and ability he invariably displayed in the discharge of his duties, and while they regret his loss, they consider that they have been fortunate in appointing Mr. Clare as his successor, who will still retain the same superintendence of the accounts as he has hitherto done.

CORRESPONDENCE.

TELEGRAPHIC FEATS.

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—Your correspondent, "W. H. N." of last week is evidently a "magnetic man," and whilst professing to do justice to the double needle and Morse, he puts the Electric and International Telegraph Company's ordinary single needle instrument entirely in the shade, and enlarges upon the superiority of Bright's bell and single needle systems.

I quite agree with "W. H. N.," that a good manipulator is the best judge of the working qualities of any telegraphic instrument, and that those who are not qualified in this respect are too apt to be led away by the opinions of individuals who are interested in some particular system; but my experience in the working of the Electric and International Telegraph Company's ordinary single needle instrument warrants me in protesting against the assertion "that its construction and code makes it slow and uncertain, and that the maximum speed attainable is only about fifteen words per minute." The single needle instrument is constructed on precisely the same principle as the double needle, and the alphabet and code employed is precisely the same as for the Morse. In the north of Scotland the single needle is the chief instrument in use, both for railway and commercial purposes; and I believe ample proof is obtainable that twenty-eight to thirty words per minute is a common speed for the transmission of expresses, &c. The Queen's Speech—of the transmission of which on all the existing systems, excepting the single needle, so much has been said in your Journal—was forwarded to two stations on one circuit, neither giving "understand," at the rate of twenty-seven words per minute, and this without taking into account numerous stoppages from various causes. Your correspondent's knowledge in this department of telegraphy must therefore be more limited than his letter leads us to infer, and I hope he will take the trouble to extend his researches in the right direction, and gratify us with the result through the medium of your Journal.

I know something of most of the telegraphic instruments now in use by the different companies; and, after a careful consideration, have come to the conclusion that the Morse, with Varley's pecker and relay arrangement, is second to none; and that if the ordinary single needle instrument was more generally used, it would take its stand next to the Morse, not only on the score of economy, but for all the qualities requisite in a commercial telegraph.

The insertion of these remarks in your next issue will, I am sure, confer a favour on all experienced single needle and Morse clerks.

Scotland, Feb. 29, 1864. FAIRPLAY.

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—Having perused your Journal of week ending 27th February, I observed a paragraph headed "Telegraphic Feats;" and in this paragraph the single needle instrument is represented to be a very slow and uncertain mode of telegraphy, and also that the maximum speed does not exceed over fifteen words per minute. I myself, having had a number of years' experience in working both this and other instruments which the Electric Telegraph Company use, beg to express my humble opinion on the subject. I consider the single needle instrument a very valuable one; and, if well manipulated, can do a great deal of work. The whole of Scotland, north of Aberdeen, is principally worked by this instrument, and it is remarkable with what rapidity the news is transmitted. The Queen's Speech was transmitted from Aberdeen to Inverness—a distance of more than 100 miles—at the rate of thirty words per minute, not accounting for stoppages by minor stations on the same circuit, and this is about the average speed which all news is sent.

As to the construction and code of the single needle instrument, I can only say they are very compact and simple, and, owing to the alphabet being the same as the Morse, renders one clerk after a little practice capable of working the two instruments.

Should you deem this worthy of a corner in your valuable paper, it may be interesting to some single needle clerks.

I am, yours obediently,

Aberdeen, March 1st, 1864. BON ACCORD.

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—I must apologise for encroaching upon your space again, but allow me to say a word or two in answer to the erroneous impressions your correspondent "W. H. N." possesses, and desires to communicate to others, upon the capabilities and merits of the Morse instrument.

He condemns the instrument because confusion is likely to result through blundering clerks. Everybody must instantly see that no instrument can possibly render correctly at one end of a line anything incorrectly sent from the other. No one could pretend that the Morse, or any instrument in fact, can make a bad clerk a good one.

This, however, is less likely to cause bewilderment on the Morse than on needles or bells, because bad writing may be deciphered if carefully scrutinised, while anything indistinctly *spoken* (as with the bells) and not understood, is lost or must be repeated.

I am afraid "W. H. N." has never seen a Morse instrument; at any rate, he understands nothing of the principle, or he could not have made such a mistake as he has done by saying,—"A yarn must be finished before the sender can be stopped."

A clerk sending a message can be arrested on the instant; in this respect the Morse is upon the same terms as the bells.

Why is conversation more impossible with the Morse than any other instrument? Any visitor who has been in an office where the Morse is used must have been struck with the rapidity of exchange of questions and answers. The maximum speed of the bells is fifty words per minute, yet ordinary and every day news is only received at the rate of thirty or thirty-five words per minute,—when, then, is the maximum attained? not in the passage of messages, I am confident.

The advantage of the Morse is that a good uniform rate of transmission can be maintained, whether for news, messages in any language or cypher, because, as I stated at first, you have the recorded signals before you to look at again and again, ensuring greater certainty of the correctness of every communication, and this is required more than a great speed on occasions only.

"W. H. N." should bear in mind it is necessary to be well informed upon any matter before one is in a position to criticise, for this reason his letter is not impartial; and as it does not contain facts, it of course fails to be instructive.

I am, sir, your obedient servant,

OLD DOUBLE NEEDLE AND MORSE CLERK.

Dover, March 2, 1864.

THE INDIAN TELEGRAPH.

To the Editor of the TELEGRAPHIC JOURNAL.

SIR,—I beg to enclose to you, with the desire they may be published, statements which I have received from Bagdad. My informant is now superintending the erection of the new Indian telegraph between Bagdad and Hilleh; he is a gentleman well known in the police services of India, and I am sure his statements may be fully relied on. The conduct of those he complains of being of some importance towards the ultimate success of the telegraph itself in that section of it, I trust you will think proper to insert the accounts in your next issue, or when convenient, a favour I respectfully beg.—I am, sir, your obedient servant,

12, Denbigh-road, Bayswater, Feb. 29. HENRY EVENNETT.

"NEW INDIAN TELEGRAPH.—*How the Turkish Government Pays and Discharges the Labourers employed by them in erecting the New Indian Telegraph between Bagdad and Hilleh.*—On the 21st of December last the paymaster appointed to pay the workmen erecting the Hilleh section of the telegraph, being short of cash, locked about forty of the poor creatures in a dirty room in the Khan. After leaving them some time in close confinement, took them out one by one, cursing their fathers, mothers, sisters, and wives; and by way of showing them his authority, &c., struck them from fifteen to twenty blows on their heads, elbows, and legs. The poor things fled—leaving, some two, some three, others four days' pay behind due to them. This mode of paying and treating the poor in the neighbourhood of Bagdad is quite common. The paymaster's name is Emar Effendi, who is a tool in the hands of Bekeer Effendi, and one or two others, the whole of whom are favourites of the Governor of Bagdad. It is thought the infamous conduct of Emar and Bekeer Effendi towards the Arabs along the route will make it useless to effect the Hilleh section for the present. Mr. Perceval, who was on the Hilleh section, has been called by the Resident at Bagdad to Busrah. As long as the Arabs thought that the telegraph was English there would be little danger from the Arab tribes, owing to the popularity of Colonel Kemball among them; but the Turks, who are jealous of the great influence of the English among their persecuted and oppressed Arab subjects of Mesopotamia, having lately published that the telegraph was the property of the Sultan, the Arabs, when they think they have been unjustly treated by the Government, will on the first opportunity destroy the line. The only chance there is for the British Government is for Englishmen to be employed to look after the line when completed, and these Englishmen should be paid by the British Government, and be placed under the orders of the Resident at Bagdad. Subsequent information received states that soon after the departure of Mr. Joyce Perceval for Busrah, an Arab tribe of over one thousand horsemen—learning from their oppressed brethren of the town the treatment they had received, and believing the telegraph to be the Sultan's property—came down and destroyed everything, stole the tools, robbed the remaining men of their money and clothes, spearing many of them, some of whom have since died of their wounds. About fifty mules were taken, as well as the tents and material required for the erection of the line. Mr. Perceval's mule, carrying his kit and bed, was alone spared, as an acknowledgment of the kindness he had shown and the protection he had afforded to the poor Arab labourers under their grievances. Many of the poor creatures were daily beaten by the officers sent to pay them, in order to induce them to run away from the work and leave their pay behind. Their friends have in the way stated taken up their cause against the Turks, to the great damage and delay of the completion of the line, as well as to the loss of the British Government."

THE TELEGRAPH CLERKS' PROVIDENT FUND.

To the Editor of the TELEGRAPHIC JOURNAL.

SIR,—In reply to "A Shareholder," whose letter appeared in your last impression, I beg to enumerate a few of the arguments adduced at the meeting of the Magnetic Company's employés, with the principal objections taken by them, to the rules of the "Telegraph Clerks' Provident Fund."

In the first place, candidates for membership are required "to produce a certificate of birth or baptism, and to state whether they have ever been afflicted with small-pox, or been properly vaccinated; if had the measles, or the hooping-cough; if had any serious illness—if so, stating the nature of such disease; and whether of temperate habits." Also, "whether candidate believes he, or she, is in good health or liable to any disease." "Whether any near relation has died of consumption, or been afflicted with insanity, &c. &c." The medical officer has also to inquire "if the candidate has any ruptures, wounds, or tumours; or whether he, or she, has ever been afflicted with acute disease of any kind, or subject to gout or rheumatism." Also, "*the age of parents*—if alive—if dead, *the cause of death; number of brothers or sisters; how many have died, and of what diseases*, and whether any relative has died of pulmonary consumption."

The arguments brought forward against these rules were, that they alone would exclude many clerks from becoming members, who would be eligible for other societies.

Rule 2 states, "that patients *must find their own bottles, &c.*, necessary to contain their medicines; and those whose diseases do not confine them at home are expected to attend at the houses of their respective surgeons before ten o'clock in the morning."

Almost any surgeon in the kingdom gives advice gratis to any person attending at his residence before 9 A.M.; and by attending at any hospital, and *taking their own bottles*, patients receive advice and medicine gratis; yet for this, and 10s. per week—not sufficient to live upon, let alone obtain the extra comforts usually required during illness—the "Telegraph Clerks' Provident Fund" require 3½d. per week, in addition to the member going through several unnecessary and humiliating formulas—such as "producing certificates of baptism, getting the medical certificate signed by a magistrate," &c. The munificent sum of 2s. 6d. per week, in lieu of medical attendance, is allowed to those who reside in a district to which no medical officer is attached.

The chief medical officer resides in Finsbury—a place no doubt selected because it is within half a-mile from the society's offices; whereas the majority of telegraph clerks reside two, three, and four miles distant. By this arrangement a saving to the fund is effected, as no medical advice or medicine can be obtained, if the illness is at all serious, for 2s. 6d. per week.

Rule 7 requires, "that the certificate for claiming sick pay must be signed by the minister of the parish in which the member resides, or by a magistrate, and is to be repeated every fortnight." In the name of common sense, can anyone say what the minister or magistrate, unless personally acquainted, knows of the illness of any individual person, let alone a telegraph clerk, who is invariably "a boarder or lodger." Such a rule as this is, I maintain, simply preposterous.

Rule 9 excludes from receiving sick pay "all members suffering from illness caused by *having been engaged in any games or sports*, nor on account of insanity, slight paralysis, blindness; nor to any female member, married, by reason of any sickness or illness the result of childbirth, or any disease consequent thereon."

With regard to the first paragraph of this rule, it must be apparent to every right-minded person that it will be greatly detrimental to the fund obtaining *male members*, inasmuch as they will think themselves debarred from enjoying the noble game of cricket, the exhilirating sport of running or jumping, the manly exercises of the gymnasium, or any healthy, and yet dangerous, recreation, so necessary to man after being shut up in a hot office for eight to ten or twelve hours—because they, the members, would be in constant fear of being hurt, and excluding themselves from receiving any benefit from the fund, which would thus leave them to starvation and pain.

With regard to insanity, slight paralysis, or blindness, I am of opinion that, when a member became afflicted with either of these calamities, the fund shall then grant the benefits so painfully needed by the poor telegraphist, who is thus doomed to life-long exclusion from society. The next consideration in this *beneficial rule* is the clause relating to "married female members and childbirth." The employment of females in telegraph offices having only been commenced but a few years since, very few have, up to the present, entered into the happy state of matrimony; but for those who are about to do so, what a consolation it is to them to know that, if they join the fund, and continue in it after marriage, with their husband's consent, they will not receive any sick pay should they experience "the great danger of childbirth." Why, sir, this is the very time they would need assistance, especially if their husbands are telegraphists—and why should it be withheld from them? This requires explanation, and many of our married clerks anxiously await it.

By rule 11, any member who has been ill and receiving sick pay for three months, is able to return to duty, and in three weeks, or less, is taken ill again, is excluded from receiving further relief until six months has expired.

I am at a loss to know where we shall find rules of a more technical, complicated, and exacting nature than the foregoing.

"A Shareholder" seems only to have taken into consideration that clerks under 20 years of age, by paying 3½d. per week, receive 10s. per week and medical attendance (or 2s. 6d. extra) in sickness. He has not considered the harass and bother of getting certificates signed by magistrates or clergymen, producing registers of baptism, &c., for the purpose of receiving the said benefits.

Some of our clerks belong to societies where, by paying 1s. per week, are allowed 18s. per week in sickness; £2 *at the birth of every child of which the member is the father*; £15 in case of fire at the member's residence; £10 at death of member's wife, and £20 at his own decease; £5 also allowed for a substitute if the member is drawn for the militia or special constable, and numerous other benefits. This refers to the "Royal Standard Society." Nearly all other societies allow a sum not under £10 for the death of the wife of a member.

With regard to the observations of "A Shareholder," that "it is to be feared that this unfortunate resolution on the part of the meeting is only another instance of the senseless jealousy and rivalry existing amongst the employés of the various companies," what will he say to the fact that "out of about 150 or more employés of the "London District Telegraph Company" (at whose offices the "Telegraph Clerks' Provident Fund" is established, and therefore more immediately belonging to them), only 60 or 70 have, up to the present, joined the fund.

This is convincing proof that the "fund," not being held in high estimation by the majority of telegraph clerks, is not due to the *senseless rivalry, &c.*, but to the want of those benefits for which the society was instituted, and towards the payments of such benefits so much money has

been given by benevolent persons, at the head of whom we must now place Her Royal Highness the Princess of Wales, interested in the welfare of telegraph clerks.

Believing "that the technicalities and requisitions introduced in the rules of the Telegraph Clerks' Provident Fund" debar the members from receiving the benefits anticipated from the nature of such a society, the Magnetic Employés Meeting passed the *unfortunate resolution* referred to by "A Shareholder."

What we require is, that the rules shall be thoroughly revised; the numerous technical points and *absurd requisitions*, at present introduced into them wholly withdrawn, and a trifling higher subscription to be paid for greater benefits to be received when members are laid up by illness, no matter from what cause it arises, excepting, of course, diseases contracted by profligacy, or members' self-neglect. When this is done, I have no doubt that the numerous patrons and patronesses of the fund will find their laudable efforts to ensure relief to the many needy telegraphists eventually crowned with success.

Trusting I have explained the rules sufficiently to allow you, Sir, to form a conclusion that the meeting was right in passing their resolution,—I am, Sir, yours very faithfully,

G. C. NEWBURY,
Chairman of the Magnetic Employés Meeting.

58, Threadneedle-street, March 2, 1864.

TELEGRAPHIC NEWS.

GOVERNMENT TELEGRAPHS.—In reply to Mr. D. Griffith, on Tuesday last, Mr. Layard stated that telegraphic messages received in cypher are never printed, while those received in ordinary words are included in the returns.

THE TELEGRAPH BETWEEN EUROPE AND AMERICA.—We understand that Her Majesty's Government have granted the concession of a right of way through British Columbia, for an electric telegraph to connect the existing United States lines with those to be extended from Russia, across Behring's Straits, a concession for the latter portion of this line having previously been given, by the Russian Government, to Mr. Collins, an American citizen.

TELEGRAPHY IN MEXICO.—The French Government are dispatching a large staff of experienced officers and engineers to Mexico, to construct extensive lines of telegraph, for which the materials are also being shipped.

THE UNIVERSAL PRIVATE TELEGRAPH COMPANY have introduced their system of communication into Belfast, a town which, from its large manufacturing establishments, cannot fail to derive much benefit from so cheap and speedy a means of communication. The system is similar to the one carried out by the company in London, Manchester, Glasgow, and other large towns. The works and lines were erected by Messrs. Reid Brothers, of the Telegraph Works, Wharf-road, City-road, London. The system is to be introduced into several other towns in the United Kingdom.

WE are sorry to hear that the Emden cable, belonging to the Submarine Telegraph Company, has been injured, as it is supposed, by a ship's anchor. Arrangements have been made for its speedy restoration, by Mr. J. R. France, the company's engineer.

THE UNITED KINGDOM TELEGRAPH COMPANY having opened their Northern Trunk Line to Newcastle, Sunderland, and Stockton, which joins on to their other main lines ~~at Leeds, to London~~, Manchester, Liverpool, Hull, Birmingham, Wolverhampton, Bradford, and nearly all the principal towns in the south of England, will in a few weeks have finished other extensions to Edinburgh, Glasgow, Leith, and Scotland generally; also their extensions in the west of England, to Bristol, Cardiff, Swansea, Penzance, and other seaports. The boon being now extended to Newcastle, we feel certain that the company will be appreciated by the public, and general support given to it, so that the United Kingdom Company's lines may ramify through every town in the kingdom; and, instead of a telegram being an expensive luxury, it may become so well known and understood by all, that it may be resorted to by the small tradesmen, as well as large merchants, brokers, and others, and in fact become almost as necessary as the penny post. Some little excitement, and considerable amusement, was afforded by the three competing telegraph companies yesterday; for no sooner had the United Kingdom Telegraph Company announced their offices opened, than large placards were immediately posted in the windows of the high rate companies, announcing great reduction of tariffs to those towns in which the United Kingdom Company have offices, and small slips of green paper were issued *ad libitum*, intimating that, until "further notice," they would remit at the same tariff as the shilling company. What this "further notice" means, we leave to the public, satisfied that honourable competition will not only benefit the general public, but also the competitive companies. We can only trust the new company will meet with the support it deserves. The opening message of the new company was addressed to the Mayor, and was as follows:—"The directors of the United Kingdom Telegraph Company to the Worshipful the Mayor of Newcastle.—The directors of the United Kingdom Telegraph Company beg to announce the opening of their lines to your town, and, in the first message through their lines, beg to thank you for the valuable aid rendered by yourself and fellow-townsmen towards its accomplishment."—*Newcastle Daily Journal.*

REFERRING to our announcement last week of the opening of telegraphic communication between Cape and Graham's Towns, later intelligence represents the line as working admirably, and much used.

THE ATLANTIC TELEGRAPH COMPANY have given notice that the seventh ordinary annual meeting of the shareholders will be held at the London Tavern, on Wednesday, the 16th proximo, at one o'clock, p.m., for the purpose of receiving a report and balance-sheet from the directors, and for the transaction of the ordinary business of the company, and a full attendance of the shareholders is specially requested.

THE Electric Telegraph between Cape Town and Graham's Town has been opened to the public, and messages are now daily transmitted along the line. On the many advantages that this grand invention will secure to the colony it would be superfluous to comment.

THE CAPE TOWN AND WELLINGTON RAILWAY COMPANY have opened their line for the use of the public. The tariff of charges is very moderate.

THE TELEGRAPH TO INDIA.

IN a second edition of this Journal of last week we had the gratification of announcing the successful submersion of the most important and difficult section of the Persian Gulf telegraph cable, 359 miles in length, from Gwadur, in Beloochistan, to Cape Mussendom, on the coast of Arabia. It appears that Colonel Stewart and Sir Charles Bright arrived off Cape Mussendom at noon on the 9th February, and sent a telegram through the cable announcing the completion of the work so far, which reached Bombay at three p.m. on the same day. The cable is represented to be in excellent working order, and arrangements were being made to proceed with the remaining sections without delay, which consists of the section from Cape Mussendom to Bushire, a distance of 440 miles, with an average depth of 80 fathoms, and that from Bushire to Shat-el-Arab, at the head of the Persian Gulf, a distance of 170 miles, with an average depth of 25 fathoms. At Shat-el-Arab the cable will be joined to the land line to Constantinople and England, while from Meekran to Kurrachee the land line is completed. From Kurrachee communication can be telegraphed to Bombay, Madras, Calcutta, and even to the frontiers of Burmah. Of the vast importance of such a work in a political and commercial point of view it is impossible to form too high an estimate, and we believe that it is only a precursor to even yet more stupendous undertakings for the extension of the advantages of land and submarine telegraphy. Although it may be urged that the Persian Gulf cable is only laid in shallow water, and that its successful submersion does not imply the practicability of deep lines, it cannot be denied but that the practicability of conveying large masses of insulated wires to remote distances, through hot climates, has been fully established by the adoption of adequate precautionary means.

The following is a description of this important cable, and of the tests to which it was subjected:—It was sheathed at the works of Mr. W. T. Henley, in twelve No. 7 gauge hard-drawn iron wires, thickly galvanized, and then thickly coated with two servings of tarred yarn, overlaid with two coatings of Bright and Clark's patent composition, which consists of mineral pitch or asphalte, Stockholm tar and powdered silica, mixed in certain proportions and laid on in a melted state, which, when cold, forms a massive covering of great strength and flexibility, totally impervious to water, and, it is believed, incapable of being destroyed by animalculæ. The copper-conducting wire is composed of four segments, drawn into a hollow tube in such a manner as to appear like a solid wire, and was carefully selected for its high conductive capacity. The conductor, which is nearly one-eighth of an inch in diameter, was covered by the Gutta-Percha Company with four distinct coats of gutta-percha, and four coats of Chatterton's compound, laid alternately, after which the core was subjected to a pressure, in Reid's tanks, of 600 lbs. on the square inch, and carefully tested for insulation, and the exact condition of each mile recorded. The following is an extract from one of the books, in which each testing was registered:—

RECORD OF TESTS APPLIED TO CORE AT GUTTA-PERCHA WORKS, APRIL 10, 1863.

No. on Coils, 155; Length of Coil, 2172 yards; Weight of Coil, 523 lbs.; Difference of real from contract weight, per nautical mile, +0 −11 lbs.; Immersed in Water at 24° centigrade, 24 hours; Temperature of Room, 15° centrigrade.

Resistance of Conductor—
No. of Elements, 6; Ratio of Balance, 100; Observed, 7·35; Reduced, per nautical mile, 6·86.

Resistance of Dielectric—
No. of Elements, 504; Time of 10 Oscillations of Needle, 29 seconds; Before Pressure—Deflection after 1 minute negative, 2·0; Resistance, per nautical mile, mill. of units, 261. Under Pressure of 600 lbs. per square inch—Deflection after 1 minute negative, 1.7; Resistance, per nautical mile, mill. of units, 308.

Charge and Discharge—
No. of Elements, 47; Constant of Instrument, 3·4. Discharge after 1 minute's electrification—Observed, 15·6; Reduced per nautical mile, 14·57. Discharge after 1 minute's insulation, 8·6; Per Centage of Charge remaining after 1 minute's insulation, 55·1.

The sections of the cable left the Thames in the following vessels:—The *Marian Moore*, on the 17th of August, with 175 miles; the *Kirkham*, on the 7th of September, with 188 miles; the *Assaye*, on the 20th September, with 368 miles; the *Tweed*, on the 24th October, with 347 miles; and the *Cospatrick*, on the 16th of November, with the shore ends, completing the 1,240 miles manufactured, all of which had arrived at Bombay, with the exception of the *Cospatrick*, which, however had been spoken to, and probably has reached her destination by this time. All the vessels were furnished with tanks, in which the lengths of cable were coiled and covered with water, each ship being provided with a small steam-engine, for the purpose of emptying and re-filling the tanks from time to time; while on board of each vessel, batteries, resistance coils, and galvanometers were provided, for repeated testings on the outward voyage.

A small steamer, the *Amber Witch*, has been fitted up with all the necessary appliances for raising and repairing the cable in case of accident, and which will also be employed for supplying provisions to the various stations.

THE RAILWAY AND TELEGRAPH INTERESTS IN PARLIAMENT.

NOTWITHSTANDING that there is a capital of £450,000,000 invested in railway projects, all that appears necessary now-a-days, to ensure further investments, is an enterprising manager, a tolerably plausible prospectus, and advertising *ad libitum*. The public appear to be aware that no difficulty will be experienced in procuring a Bill for a railway anywhere, except through the centre of St. Paul's Cathedral, though we are not certain whether some of the more ambitious promoters of these schemes have not consigned this magnificent edifice, among other buildings, for demolition. The days of the metropolitan railway mania, however, appear to be numbered. A meeting of some of the most influential merchants and bankers of the City was held on the 4th inst., whereat a resolution was carried to the effect "that the limited area of the City of London, its immense and rapidly-expanding trade, should be protected against the intrusion of any railway not absolutely requisite for the public," &c., and an association was formed to enforce the views expressed at the meeting. The representation of the railway interest in Parliament is astounding, and when any question affecting this description of property is raised, there are

no fewer than 153 railway directors in the House of Commons, and 47 in the House of Lords, prepared with an unanimous "aye" or "no" immediately—an influence sufficient to ruin the nation. The plans now before Parliament, if carried out, would absorb an amount of capital equal to one-half the present investments, owing to the immense value of property through which the projected lines will pass. It is extraordinary that an institution, which scarcely existed thirty years ago, should have, in this brief space of time, acquired so inordinate a parliamentary representation.

How stands the telegraph service in this respect? There is a capital of about £10,000,000 sterling invested in this description of property, represented by seven directors in the House of Commons, a relatively satisfactory condition; but the number is totally inadequate to the prospective development of the system. It will be remembered by some of our readers that, towards the close of the year 1859, "the Lords of the Committee of Privy Council for Trade caused to be appointed a committee, consisting of gentlemen well known for their scientific attainments, and great practical knowledge, to enquire into 'the best form for the composition and outer covering of Submarine Telegraph Cables.'" As might be expected of thoroughly business-like men, they set to work, and the result of their labours is a report in the shape of some 500 folio pages, detailing their numerous experiments and enquiries, indeed a most elaborate treatise on submarine telegraphy. From the mass of information here collected, we had expected that the subject of telegraphy would be brought under the consideration of Parliament, and some steps taken to promote its adoption by the Government, and its extension as a means of communication with other parts of the world. But not a syllable has been uttered, not an action wrought since the report was published. Of late the House of Commons has devoted a considerable portion of time in investigating the claims of various designs and contrivances for the best method of constructing small-arms, rifled cannon, and iron-clad ships, and enormous have been the expenses incurred in the various experiments to determine the most destructive instruments of war; while telegraphy, which is destined to promote the arts of peace, is totally ignored. It is time that vigorous action was taken in this matter; but until some few eminently practical men are sent to Westminster—men who can demonstrate to the country the importance of the service they represent—so long will telegraphy be enshrouded in mystery, and all efforts to aid in its development as a preservative of the peace of Europe—in fact the world—be met with prejudice on the one hand, and indifference on the other.

We have already seen how rapid has been the development of the railway system, and to what its great success is to be attributed. Our strength has recently been augmented by the return of Mr. Moor (Chairman of the Mediterranean Extension Telegraph Company) for Brighton, and it is to be hoped that telegraphy will receive a fair amount of consideration in Parliament, and that the friends of this enterprise will be prepared with some thoroughly representative man at the next general election. We are already indebted to Lord Alfred Paget, Lord Alfred Churchill, Sir H. J. Leeke, K.C.B., &c., J. C. Ewart, Esq., Samuel Gurney, Esq., John Pender, Esq., and others, for their influence to extend the system of electric communication; but we shall not consider that telegraphy has made any great national progress until it is adopted by the Government as the regular medium of correspondence with our representatives in other parts of the world. Every accuracy and privacy is maintained in the instrument-rooms, and the wire might be used advantageously in all our political relations with other Powers; and we hope that very shortly the attention of the country will be directed to the immense reduction which might be effected in this branch of the national expenditure by the general adoption of the telegraph.

ON THE EFFECTS OF EXTERNAL PRESSURE ON INSULATION.

By LATIMER CLARK, Esq., M.I.C.E.

It being a matter of much interest to ascertain what might be the effect of the enormous external pressure to which deep-sea cables are necessarily subjected, many experiments were made on this point; the uniform result obtained was that the insulation was greatly and instantly increased, or, in other words, the conductivity of the insulator was diminished by pressure, and the improvement in insulation thereby induced appeared permanent so long as the pressure continued to be applied, but no longer. Wires of different materials were subjected to pressure for lengthened periods, but in no case could any evidence of permanent injury or change be obtained. India-rubber in a masticated state is known to be an absorbent of water, but the effect did not appear to proceed with greater rapidity under pressure than under ordinary circumstances. Very great difficulty was experienced in conducting these experiments satisfactorily, principally owing to the difficulty in making the joints. The impression derived from them was very decided, that there is no reason to apprehend any difficulty in deep-sea telegraphy as regards the insulation of the material generally, or of the joints.

The apparatus consisted of a small hydraulic press loaded with weights to maintain the requisite pressure, and of two parallel iron pipes, each 1-16th of a mile long, to contain the wire under experiment. The press was formed of an upright steel piston exactly one inch in diameter, working in a cylinder of wrought iron, and having a stroke of 18 inches. It was guided in its motion by a cast-iron frame. On the top of this piston was placed a saddle, from which depended four chains carrying a scale pan, in which were placed iron weights. The pipe leading to this apparatus was connected with two parallel hydraulic pipes of wrought iron, in which the wires under examination were placed. These pipes were each 110 yards, or 1-16th of a mile in length, and when not in use were open at both ends. They were laid side by side on a platform, which was about three feet higher at the distant end than at the press, to allow the ready escape of the air.

The wires under examination were drawn into these pipes, and the ends made secure by a stuffing-box of gun-metal. A length of No. 16 copper wire, covered with Wray's compound, of the diameter of ¼ inch and 220 yards in length, was drawn into the hydraulic apparatus, and the ends being secured, a pressure of 3 tons on the circular inch = 8,556 lbs., or 3 tons 16 cwt. on the square inch, was applied by means of the force-pump. This pressure is equivalent to a depth of 3,190 fathoms of sea water. A battery power of 512 cells was applied, and the insulation measured by the fall of the static tension, as shown on a "Milner's electrometer." The deflection of this instrument with a tension of 512 cells was 52¼°. The time was noted in which the needle fell from 52¼° to 49°, the temperature was 47°, and the time midnight. Before the pressure was applied the length of wire covered with Wray's compound took twelve minutes in falling from 52¼° to 49°. The pressure was then applied, and the insulation immediately measured again, and it now required twenty-five minutes for the tension to fall as before, from 52¼° to 49°; the insulation was twice as perfect as before. The pressure was then removed, and a third observation was made, when it was found to occupy eighteen minutes in falling to the same tension.

The following experiment was made on a piece of gutta-percha wire 110 yards in length, and of the same dimensions:—The pressure applied in this case was 3 tons on the square inch, or equivalent to 2,555 fathoms of sea water. The temperature was 54°, and the time midnight. The insulation was measured by the Milner's electrometer, and the time was noticed, during which the tension fell 10°; this was equivalent to a fall of the tension from 512 cells to 384 cells. Before the pressure was applied five observations were made, viz.:—

Time occupied in falling 10° on Milner's electrometer.

22 seconds.
23 "
23 "
23 "
23 "

A slight but unknown pressure was then applied, and the time of falling increased to 33 seconds; a little more weight was put on.

and the time increased to 60 seconds; with a further weight the time increased to 75 seconds; the weight was then taken off, and three observations were made, and each gave 25 seconds as the time for falling 10°. A portion of the weight was again added, and another observation gave 87 seconds. The whole pressure of 3 tons on the square inch was now added, and three observations taken, which gave—

Time of falling 10°.
110 seconds.
100 "
115 "

The pressure was kept on 15 minutes, and taken off for 7 minutes; five observations were then made, the results were as follows:—

Time of falling 10°.
22 seconds.
22 "
22 "
23 "
23 "

The pressure being again put on, three observations were taken of the time, which were as follows:—

Time of falling 10°.
120 seconds.
128 "
132 "

The pressure was continued 15 minutes, and was then removed for 10 minutes, when five more observations were taken, with the following results:—

Time of falling 10°.
24 seconds.
25 "
27 "
26 "
27 "

In another experiment made on the 31st of July, 220 yards of gutta-percha wire were submitted to pressure in the same manner as before. Before the pressure was put on three observations were made on the insulation; in each case the time occupied in falling 10° on Milner's electrometer was 15 seconds. A pressure of 3 tons on the square inch was then applied, and the insulation immediately taken again; in three successive observations the time of the tension falling 10° was 52 seconds. The pressure was then removed, and three more observations gave—

Time of falling 10°.
17 seconds.
17 "
16 "

In one of the above cases the insulation of the gutta-percha was increased five times, and in the other three times, and this effect was constant in all experiments, though not quite uniform in amount. The special material of the Gutta-Percha Company gave similar results. India-rubber improved also in the same manner, but it required care in measurement on account of surface moisture. These experiments, when conducted with the ends of the wire exposed to the air, could not be relied upon; it was necessary to lead them into a metal box with a glass cover, dried by chloride of calcium, and containing the electrometer, which was read through the glass, suitable air-tight sliding wires being provided for making and breaking the contact.

[We had the opportunity of witnessing the whole of the above interesting experiments.—ED. T. J.]

POROUS CELLS.

WE believe that the first application of porous cells for batteries in this country was that by Mr. Fothergill Cooke, in 1837. The cells were manufactured at the well-known works of Messrs. Davenport. Great improvements have recently been effected in the manufacture of such cells, which have rendered the battery more *constant* and continuous in its action. Mr. Culley, in his valuable work, makes the following interesting and practical observations on the subject:—"If the porous cell be of a bad quality, containing coke or metal dust, the copper will be deposited in patches upon it. When these patches of copper touch the zinc they form local circuits, like the particles of foreign matter contained in the zinc itself, wasting both sulphate of copper and zinc. When the porous cells become crusted with copper, they should at once be removed. The zincs should never be allowed to touch the porous cells, for copper will immediately be deposited on the porous cell, so as to form a local circuit with the zinc. The porous cells do not entirely prevent the mixing of the solutions; in fact, after a time, much of the copper solution escapes into the zinc cell. The zinc decomposes this copper salt, and copper in a metallic form, or as a powder or mud, is deposited on its surface, or falls to the bottom of the cells, while the acid, set free, dissolves the zinc. This deposit weakens the action of the battery, and in some cases, when the cells or pots are very porous, as much zinc is dissolved and sulphate of copper used when the battery is idle as when it is at work. The zinc cell should be much larger than that containing the copper, in order that the sulphate which leaks through may have more liquid into which to diffuse itself, and thus become more dilute, the zinc will then act upon it less rapidly. The liquid passes through the porous cell from the zinc to the copper, in virtue of a singular property, common to all porous substances when dividing dissimilar liquids, called 'osmose,' and it will frequently rise in the copper cell an inch or more above the level. The current aids this movement."

It will be seen from the above, that the quality of the porous cell exerts considerable influence on the efficiency and economy of the galvanic battery; hence the desirability of having the cells of the best possible material and manufacture. We have had to conduct experiments with batteries having no less than 512 porous cells, employed for eighteen months without having to replace but a very few from having become defective. Those cells are now extensively employed in the Muirhead improved batteries, both at home and abroad. Messrs. A. Singer & Co., of the Vauxhall Pottery, have forwarded us, for inspection, specimens of their improved circular porous cells, which are of superior manufacture, great care being taken in the preparation of the material, in excluding all impurities, and in the process of baking. In testing a cell for its porous quality, we found that it fully sustained the high character the manufacture has already received from several of our leading electricians. We do not, however, attach much importance to the glazing around the rim, as we have had an opportunity lately of examining several hundreds of cells, glazed and unglazed. The glazing appeared to us to make but little difference in the accumulation of the salts.

Silver & Co.'s improved porous cells are in use by the London Chatham and Dover, London Brighton and South Coast, and other railway and telegraph companies at home and abroad. This cell, from the nature of its construction, is one of the most constant and durable that has yet been introduced; its great superiority over the ordinary earthen porous cells hitherto used consists of the readiness with which the porous quality of the cells can be regulated to any desired quantity, the small consumption of sulphate of copper, and the duration of time they will continue working without any alteration. Cells of this description have been in continuous use in the telegraph department of the London, Chatham, and Dover Railway Company from October, 1862, up to the present time, with scarcely any perceptible deterioration excepting the zinc plates; it is, therefore, peculiarly adapted for any description of climate, both on account of its non-liability to breakage, durability, and consequent small cost for maintaining, which, after first cost, is comparatively nil.

THE SOUTH-EASTERN RAILWAY COMPANY'S TELEGRAPH.

THE Telegraph system, which has from an early date been in operation on the South-Eastern Railway is, as most of our readers are aware, the exclusive property of the Company. It consists of no less than 306 miles of telegraph, and the total length of wire exceeds 1,500 miles. The number of speaking instruments employed for public and railway purposes, at the present time, is 188. For the working of the trains there are in use 411 signal bells. Mr. Walker, in the discussion which followed the reading of Mr. W. H. Preece's valuable paper on Railway Telegraphs at the Institution of Civil Engineers, made the following remarks on the subject:—

As the extensive system of telegraph signalling in operation on the South-Eastern Railway had been only slightly mentioned in the paper, he deemed it incumbent upon him to make a few remarks, so that the members of the Institution, and the telegraph world generally, might be made better acquainted with it. In doing this, he should, unavoidably, have occasion to refer to it in plain terms, as his own system. It was his own, inasmuch as

he originated it, and it had been perfected under his care; he therefore felt a strong interest in it. It was not, however, the subject of a patent, so that he had no pecuniary interest in it.

From the remarks made by a previous speaker, it would have been gathered that "sound upon bells" was the basis of the system of train-signalling he was about to describe; without this, a leading feature would be gone. It would be right to place this matter historically correct before the Institution, in order that the origin of the bell-signal system, for which "Honourable Mention" had been awarded at the International Exhibition, 1862, might remain on record. In the autumn of the year 1851, a want was communicated to him by the then manager of the South-Eastern line. In his reply, of which the following was a copy, Mr. Walker described the system proposed to be introduced; and he had not since seen any reason to alter his opinion of its efficiency for train-signalling,

"South-Eastern Railway.

"Electric Telegraph, Tunbridge, Oct. 29th, 1851.

"My dear Sir,—In respect to the signalman at the Spa-road indicating the character of the up-trains to the switchman at the entrance of the South-Eastern and Brighton terminus at London, and to the latter having power to order either train to be stopped at the Spa-road:—The distance is 820 yards. It would require two* wires, which could easily be erected. I should construct two bells, of a totally different character to those used for the telegraph, and should use a different kind of battery.† One blow on the bell would indicate a Croydon train, two a Brighton, and three a South-Eastern. I would so construct the apparatus, that it could be relied upon. The expense would be very little, and it could not easily be deranged,

"Yours very truly,

"To Captain Barlow, (Signed) CHARLES V. WALKER,
"Superintendent." "Engineer and Superintendent of Telegraphs."

That letter described the foundation of the bell-system, as now in operation throughout the South-Eastern Railway. The first pair of bells were fixed and used January 22-31, 1852. The specification of Mr. Tyer's first patent was dated July 20th of the same year. At the present time, the South-Eastern line was protected in every possible manner by bells of the kind described—there were 330 bells in operation—some being connected merely in pairs, some with intermediate bells, and in other ways. Of these, eighty-four were provided with counting indexes, which indicated the number of blows sounded, and the remainder were plain. The total length of the South-Eastern line, thus protected, was 275 miles; and eleven other miles of the line were furnished with Mr. Tyer's instruments. Signal-bells were in course of erection‡ on the Caterham branch of nearly five miles in length. The Angerstein branch, of half a mile, which was without bells, was not used for passenger traffic. The Whitstable branch, of six miles, was provided with a pair of telegraph instruments, which were little used for speaking purposes, but served for signalling trains. From Ash to Shalford, upwards of eight miles, belonging to the South-Western Railway Company, but over which South-Eastern trains ran, electric signalling was not employed.

With respect to the cost of the telegraph signal-bell system, and the amount that had been expended by the South-Eastern Company upon it, in order to promote the safety of the traffic, he might state that the total cost on the 275 miles had been nearly £3,650, or at the rate of £13 5s. 3d. per mile, including wires, bells, and batteries complete. There was at the rate of one bell and a fifth for every mile, or one bell to every 1,466 yards; and the total cost on each 1,466 yards was £11 0s. 11d. The average cost per bell, including the "pecker" or ringing-key, taking the bells one with the other, plain and index, had been £4 6s. 6d.; and the cost complete, including batteries, had been £5 10s. 3d. The train signal-bells were in charge of the station-masters and the ordinary signalmen, so that the working expenses were not thereby increased to any appreciable extent. Loud-sounding bells, at least four or five inches wide across the mouth, were employed. The principle to which he had referred in his letter to Captain Barlow was, to wind the coils with No. 16 or No. 18 wire gauge, which was at that time an unusual size for an actual working telegraph instrument. The hammer which was attached to the keeper of the electro-magnet, was the only moveable part of the bell apparatus. The signals were given by the number of blows struck; the code for all ordinary purposes, called in practice "the general code," being one blow for an up train out, two blows for a down train out, and three blows for a train in. For blocking the line, the bell-signal was five blows; clearing the line after a block, three blows, or the in-signal given and taken twice. One fundamental and essential condition was, that every signal made by one man should be correctly repeated by the other man. If A made a signal to B, and the repetition was not given, it was an indication either of misunderstanding, or of something being wrong. No signal was allowed to be complete, until it was recognized by the return of the same number of blows that had been sent.

Independently of the above application, which was the simple and ordinary process of train-signalling from station to station, these bells were used in many ways and in a great variety of places; in fact, they were almost universally applicable. At the London platform, bells were the effective instruments for supplying a certain want. It now and then occurred that a South-Eastern tidal train and a Brighton train were due to start from the respective London platforms at about the same time. Should the South-Eastern tidal-train be unable to start to the minute, the inspector on duty had access to a "pecker," which enabled him to strike a certain number of blows, three, on a bell in the box of the signal-man who had the control of the entrance to both stations. This was an intimation that the South-Eastern train was not quite ready, and that the Brighton train might be allowed to go out. Again, at every level crossing, without exception, on the South-Eastern line, bells were placed in circuit in the gate-house, to be heard, but not to be answered. In this way indication was given that a train was approaching, either from A or from B, according to the number of blows; and the gate-keeper, hearing the sound of the bell, was made aware when the gates must be closed, till the approaching train had passed. In cases where the gate-house was close to a station, the bell was so connected that every signal sent to the station to which the gate belonged, from the station either to the right or to the left, was heard at the gate-house. Then, again, on the London Viaduct, there were two up lines to protect, and three different kinds of up trains to be distinguished. Between London and Redhill, one blow was given on the bells for a South-Eastern train, and two blows for a Brighton train. On the Bricklayers' Arms branch a still greater distinction had to be made. There were four kinds of up trains, and two kinds of down trains; and blows on the bells were arranged to meet these various circumstances. It was not desirable that bells should be required to express so many different things; but on that branch it was impossible to avoid it. The up distinctions were, South-Eastern engines, empties, and goods, and Brighton goods; the down, North Kent and main line. Again, at Hastings, Canterbury, and Paddock Wood, moving trains were indicated to the porters by a bell placed on the platform of the several stations. The men right and left of the stations did the signalling, a platform bell being placed on a continuation of the wire; so that all that was taking place at the signal-box, and required to be known by the station-master, was communicated by the bell. If a train was signalled as coming from St. Leonards or Winchelsea, the station-master at the Hastings platform knew what train to expect. At Ashford there were two junctions, which was another cause of complication, and several different signals had to be given by the bells. They were arranged in different groups, and spoke by the number of blows given. At Beckenham there was another extension of the same kind; and although the signal-man was somewhat removed from the station, the station-master heard by a platform bell the signalling that was going on in the signal-box, and had all the information he required of the various kinds of trains. At Margate the signals sent from Ramsgate were taken at the signalman's box, some distance from the platform, but these were heard also at the station. At Folkestone and Dover there were similar arrangements. Then there were small stations, which were closed at night, when the communication with the bells ceased. In such cases the signalling was done by the stations right and left, which were switched into connection before closing. Repairs were now going on in the Bletchingly Tunnel, during which a bell was placed in circuit in a hut at the tunnel mouth, within hearing of the men; and they were by its means made aware of the approach of a train.

One peculiarity about these instruments was, that they appeared to be the only kind of telegraph instrument that could be actually used, and that had been experimentally and successfully tried, with balanced currents. He communicated to the Royal Society, in 1857,* a short notice of the mode of working these bells with balanced currents. He subsequently found that a patent, of which he had not before heard, had been taken out by a Mr. Walker, of Glasgow; on looking to the specification, he could not, however, discover that any instrument had been conceived by which the system could be worked; nor could he ascertain that any use had been made of the patent. When the bells were arranged with balanced currents, the guard of a train, which might have become disabled between two stations, had merely to fasten a wire to the bell line-wire, and each time he touched the rail with the other end of the wire, the bells at the stations on each side were rung. No batteries or apparatus of any kind had to be carried with the train.

The system of signalling was so efficiently carried out on the South-Eastern line, that such a use of the bells as he had just described was hardly to be looked for. If a train did not arrive within a few minutes of its time, it was tolerably well known that it had broken down. However, if necessary, nothing more was required for putting all the bells in use into this balanced condition, than to take a couple of wires off their terminals, and to interchange them. Another advantage of the large wires with which these bells were wound, was, that although the gutta-percha covered wires buried in the London Viaduct were perishing,—those on which the bells were at this moment working giving what was technically known as "dead earth,"—still the bells worked very well through these moribund wires. One of the bells exhibited to the meeting was plain; and the other had the counting-index already mentioned attached to it. That was his idea of a really useful index. The bell-system had been so thoroughly carried

* The second wire was not found to be necessary, the viaduct-earth being sufficiently good.

† This was the graphite battery (since platinized), for which a prize medal was awarded at the Great Exhibition, 1851.

‡ Since these remarks were made, the Caterham branch has been fitted with bells.—C. V. W. Feb. 2, 1863.

* Vide "Proceedings of the Royal Society," vol. viii. p. 412.

out, that in some of the signal-boxes there were two, three, and in rare cases, as many as four bells. The bells differed in tone, and in the position they occupied. Should the noise of an engine blowing off steam, or any other cause, make it uncertain to a signalman how many blows had been struck upon the bells, or which bell sounded, he would find them registered by the index, which pointed to the number on a dial. It was a simple mechanism—a pair of pallets and a scape-wheel on the arbour, which carried the hand of the index to the precise number of blows struck upon the bell.

With regard to the semaphore to which Mr. Tyer had alluded, and which was for making the very signals proposed by Mr. Preece, it was constructed by him merely as an illustration about eight years ago, and was used at Tunbridge for some months. The pair of instruments now exhibited were alternate. They were shown at the Paris Exposition in 1855. The instrument was of very simple construction, consisting merely of a galvanometer needle, with a semaphore index as an outside needle; and did not differ in principle from Mr. Cooke's needle, originally used on the Norwich and Yarmouth line, and since employed on the London and North-Western Railway. Instead of an outer needle pointing right or left to written words, it carried an ivory arm on the top of a semaphore pole to be set up or let down, and required a persistent current to retain the arm in one of its positions, as Mr. Cooke's did for both positions; which should be avoided when practicable.

Of all instruments which had an index Mr. Tyer's was the simplest and most certain. The manner in which that index was arranged was very ingenious. It was a soft iron needle, hung loosely at the end of the core of the electro-magnetic coil; this was an original and good idea, and such a needle would be less liable to derangement than many others. These needles had worked admirably on the eleven miles of the South-Eastern Railway before referred to. It must be borne in mind that these indexes did nothing more than move to the right or to the left; more than this was required, and, as it had been seen, by the bell system much more was done. The bell system had been introduced by Mr. Bartholomew on the Brighton line; he had, however, made his bells much smaller, and had added an index with two positions. Mr. Radall had also adopted the pure bell system on the London, Chatham, and Dover Railway, employing smaller bells; but Mr. Walker thought it would be more convenient in all respects to adhere to the use of large bells.

The objection he had to an index was this:—His idea of train-signalling was, that a good understanding and communication should be established between two neighbouring stations. In explanation of his views, he had forwarded to the Institution of Civil Engineers, in the year 1856, a paper on Train-Signalling; but the subject not being then attractive, it was not read. On looking through this a few days ago, he found that there was scarcely a word in it which he would now strike out; and the paper could as profitably be read now as then. He would merely refer to it in illustration of the principles of train-signalling adopted on the South-Eastern line, and the instruments with which he had brought those principles into practice. The bells now in use were identical in their minute details with those therein described. He read from the paper four conditions, which appeared to him then, as they did at the present time, to be the basis of all train-signalling. There should, in the first place, be a good speaking understanding between the men at two neighbouring stations, A and B; and the four telegrams which were necessary between them were these—1st. "May I send a train?" given by station A striking one blow to B; 2nd. "Yes, you may," one blow struck back by B. Nothing could be simpler. The blow was a loud one, distinct in its sound, and readily understood. The third communication would be from B. 3rd. "The train you sent is in safe," intimated to A by three blows; to which the fourth message sent back from A—4th. "All right; I understand train is in." A repeating B's three blows. These four signals were booked by each station; the time at which each signal was completed being entered in the proper column, so that a double permanent record was secured. The admirable manner in which these messages were booked was shown in a late Government inquiry. Without unduly boasting, he might state that no collision had ever occurred on the portions of the South-Eastern line where these bells were in use, which was no bad illustration of how successfully they worked.

One chief reason why he continued to object to semaphores and indexes was, that the second of the above-named four signals was always contradictory, and did not mean what was intended to be conveyed. The first question was, "May I send a train?" The answer with the combined bell-and-index system would be, "Yes, you may not:" that was, whilst the bell reply said "Yes," the semaphore went up, or the index went over, which meant "No." It was true the "No" was understood to refer to any train that might follow the one in question, although it did not say so; but some day the index might say "No," and mean "No." In his mind, the signal was complete as soon as the men had exchanged signals, and had booked them.

To work the instruments, bells, &c., 6,900 battery cells are employed, of which 5,390 are platinized graphite. Mr. C. V. Walker, F.R.S., the chief superintendent and electrician of the company, finds that by platinizing the graphic plates the liberation of the hydrogen-gas from their surface is much facilitated, and that polarization, one great defect of single fluid batteries, is thereby diminished. The cost of the process is stated to be about one halfpenny per plate of the usual size of 7 inches by 3 inches. The platinized plates are also found to keep much cleaner than simple graphite plates.

The system of telegraph consists in all of 299 stations, and are thus classified:—1. Public stations, 94; railway stations, 205; = 299. 2. Speaking stations, 138; non-speaking, 161; = 299. 3. Bell stations, signalling, 152; do., hearing, 96; non-bell, 51; = 299. 4. Bell stations only, 161; bells and instruments, public, 56; do., railway, 31; instruments only, public, 38; do., railway, 13; = 299.

THE INTERNATIONAL EXHIBITION, 1862.

(Continued from page 115.)

6. *Special Arrangements (not Automatic) of Sending and Receiving Apparatus.*

Messrs. Siemens, Halske, & Co., M. (United Kingdom, 2,959), exhibit a complete set of apparatus for the transmission, reception, and translation or retransmission of Morse signals through long submarine lines. No compensation or contrivance of any kind is provided for increasing the speed with which signals can be made to succeed one another without confusion; but provision is made for discharging the lines at the end of messages, and for preventing, under any circumstances, the discharge from passing through the home relay. The set for an intermediate station consists of—1st, two polarized relays of the construction already described; 2nd, two ink-writers similar in most respects to those already described, but so arranged as to be self-starting, and specially modified with a view to translation and to the discharge of the line into which signals have been transferred at the end of a message; 3rd, two Morse keys of peculiar construction; 4th, two lightning dischargers, two galvanometers, two commutators, and two distributors to alter the connections for direct reception or for translation.

The chief points of interest are to be found in the ink-writer and the key. The ink-writer is made self-starting by a very simple arrangement. The local current established by the relay passes round a second supplementary electro-magnet entirely distinct from that used to move the writing lever. The armature of the second electro-magnet is on one end of a rocking lever, the other end of which carries a little spring, resting against a drum, fixed on the axis of the last of a train of wheels, and acting as a break to stop the clockwork. The spring is lifted and the clockwork released, so soon as the local current is established, and the armature attracted. When the local current ceases, this break is prevented from immediately falling back on the drum by a little bent lever or boot, which slips down between the break lever and a second slowly revolving drum, at the instant the first lever is lifted. This little boot keeps the break-spring off the first rapidly revolving drum until slowly pushed on one side by the second drum, whereupon the break-spring falls again, and stops the clockwork. This, however, occupies several seconds, and if during all that time a single signal is received, the break lever is again lifted to its full extent, the boot slips back to its extreme position, and the stoppage of the clockwork is again deferred for several seconds. In this way, during the whole reception of a message, the little boot continually slips back, dancing on the second drum; and the clockwork, therefore, continues to revolve as long as signals continue to arrive, but will be stopped by the break-spring a few seconds after the reception of the last signal. It is difficult without a drawing clearly to describe the action of this very simple and perfectly effective little contrivance. The main writing lever is arranged so that it can be used to translate or retransmit the message received into a second section of the cable, and the break lever, as it may be called, fulfils two important functions in connection with the translation; it is permanently connected with the line into which signals are to be transferred, and is, of course, insulated from the framework of the machine. So long as it remains held up by the boot during the reception and translation of a message, it breaks a connection between the second line and its relay, so that the entering current does not pass through the relay; but no sooner does the break lever fall down than the connection between the line and relay is again completed, so that any answers sent by that line can at once be received by its relay, and translated back into the first line. Moreover, before connecting the end of the line with the relay, the lever and boot puts it for a short time in connection with earth, so that no discharge shall be sent through the relay to its detriment.

This is managed by a little piece of platinum on the centre of the boot; the boot is chiefly made of ivory, an insulator, and when either the break lever is quite held up by the boot, or when it is pushed quite out of the way, the metal drum below is only in contact with this ivory, so that the second line, although it is connected with the lever, is insulated at this point as well as elsewhere; but when the boot is halfway between these two points, a piece of platinum on its foot passes over a platinum ring on the metal drum, and makes contact between the lever and the metal drum, and so between the line and earth. Thus, a series of very complete combinations is effected by very simple means. The contacts required for translation are obtained, as already mentioned, from a lever in connection with the armature of the ink-writer.

The translator sends positive and negative currents with two contacts only, by means of a double battery. The traverse of this lever is considerable, and the time spent in this motion is entirely lost for the battery contacts. A great portion of this lost time is saved by a little spring on the lower side of the translation lever; the lower contact is made against this spring some time before the lever has reached its lowest position, and continues some time after it begins its rise. This spring can be so adjusted as to make the lost time very small, and the lower contact which sends the printing current can even be made longer than half the complete dot period. This counteracts the tendency of the dots to shorten at each successive translation.

The relays, as well as the ink-writers, are intended to work with reverse currents, which are sent from two distinct batteries by two simple contacts; one contact puts the line in connection with the positive battery, and the other with the negative battery. It is clear that a greater number of cells must be kept constantly in use for this plan than for that used by Sir Charles Bright, where positive and negative currents are indifferently sent from the same battery; but it does not follow that the consumption of zinc and sulphate of copper will be much greater, provided always the local action in the batteries be small, for each of the two battery circuits is only closed for half the time during which the single battery is closed, when one only is used. Messrs. Siemens state that, after considerable experience of both methods, they prefer the plan of sending reverse currents from two batteries, as simpler than the use of a reversing key.

The peculiarity of Messrs. Siemens' submarine key consists in a lateral motion given to the handle, by which, at the beginning of each message, the connection of the line with the home relay is first broken; secondly, the line is connected for an instant direct with the earth—a connection which, at this moment, is useless; and thirdly, the lower contact is connected with the negative battery. The upper contact is permanently in connection with a positive battery, and the lever with the line. If, therefore, the key be now used in the ordinary way, signals are sent by reverse currents. When the message is ended, the handle returns to its original position, and while returning, the lateral movement first removes the negative current from the lower contact, with which the lever, and consequently the line, is in connection when the handle is untouched; secondly, it puts the lever and line for a moment in connection with the earth, which discharges the line, and prevents any shock from passing through the relay, with which the lateral motion finally connects the line, leaving it in a position to receive signals from the distant station. The connections can be altered as required by conical plugs. The commutators, galvanometers, and lightning guard do not call for a special description.

The workmanship of the whole is excellent, and in the hands of skilled clerks, such as alone ought to be employed on submarine lines, will give very satisfactory results. It is, however, singular that this apparatus should contain no special provision for meeting the difficulties due to retardation from lateral induction in long submarine cables.

Messrs. Siemens, Halske, & Co. also exhibit Morse instruments, so arranged as to admit of the simultaneous transmission of messages along one wire in both directions; this apparent impossibility can be accomplished by very simple means, and Messrs. Siemens' arrangement is only one of several which have been proposed.

For convenience we will call the two stations A and B, and will suppose that ordinary Morse signals are to be sent with alternate battery and earth contacts, made by the usual Morse key, the lever of which is in connection with the line.

The relay has two coils which, with equal currents, will produce an equal effect on the armature; one of these coils is placed in circuit between the key lever and the line; the other coil is placed in a second circuit between the same lever and a set of resistance coils, the other end of which is in connection with earth. Each set of resistance coils is so adjusted as to be equal to the resistance of the line. The ends of the relay coils connected with the lever are so chosen, that two currents flowing from the lever through both coils shall have an antagonistic effect on the armature, and if the two currents are equal, the armature will be unmoved. The arrangements of the two stations are symmetrical. Now, let A signal to B; A depresses his lever, making contact between the line and the battery; the current flows from his battery into the lever, where it divides, one half flowing along the line after passing through one coil of A's relay, then through one coil of the relay at B, and to earth through B's lever; a perfectly insensible portion flows through the second coil of B's relay, the armature of which moves under the influence of the single coil, and B receives the signal in the usual way. The other half of the current flows through the other coil of A's relay, then through the resistance coils, and so to earth. This second half of the current is exactly equal to the first, since the resistance of the two circuits is equal, and the two equal but antagonistic currents leave the armature of A's relay unmoved; now, while A's lever is depressed sending a current, let B also depress his lever to send a signal to A. The current from B's battery splits in the home relay through the two coils, the one half neutralizes the current which is received from A, but the other equal half, passing round the second coil of the relay *from* the key, produces exactly the same effect on the relay as the received current would when passing through the first coil *towards* the key. Thus the armature of the relay continues deflected, or begins to be deflected, exactly as if it simply received A's signal through the first coil.

It has been observed that the current sent by B into the line neutralizes the current sent from A, and the consequence in B's relay has been shown; but this neutralization is also felt in A's relay, where no current now passes round the first coil. On the other hand, one half of the current from A's battery passes round A's second coil, and being unbalanced by any current in the first, works A's relay, and this current flowing outward from the key through the second coil, produces exactly the same effect as a current flowing inwards from the line to the key through the first coil. Thus we see that, whether the lever at A's station is up or down, in contact with earth or the battery, its relay works whenever the second station sends a signal. It is worked directly by the received current, in the usual way if the lever is up, and indirectly by its own battery if the handle is down. But the lever may be in a third position—*i.e.*, between the two contacts; in this case the received current passes in through the first coil to the lever, and then out through the second coil to the resistance coils, and so to earth. The two coils in this case produce effects which must be added, instead of subtracted; but, on the other hand, the resistance of the whole circuit is doubled, and the current consequently halved. The armature of the relay will, therefore, experience exactly the same attraction in this third case as in the two others. If, therefore, the resistance of the resistance coils of each station be kept exactly equal to that of the line, signals will be received in exactly the same manner, whether the key lever be up, down, or in an intermediate position; in other words, whether it is making a battery or an earth contact, or neither.

This ingenious contrivance has not been found practically useful. The resistance of lines varies considerably as the weather varies, and the clerks either cannot or do not care to make the corresponding changes required in the resistance coils. The resistance of the batteries should also be insensible compared with that of the line, and the electro-motive force of the two batteries should be equal; conditions probably somewhat difficult to fulfil in practice.

The British and Irish Magnetic Telegraph Company, M. (United Kingdom, 2,864), exhibit an electro-acoustic telegraph, used at all stations where much business is transacted by them. The system was introduced by Messrs. Bright. Both Professor Wheatstone and Dr. Steinheil, of Munich, combined an acoustic system with their early telegraphs, but the present is the only apparatus of this class practically used in Europe. The sending apparatus, as already mentioned, consists of a pair of finger keys capable of rapid manipulation, and so connected that the operator sending does not pass his own currents through his acoustic apparatus, which on the key rising is ready to receive signals from the other end. One key passes the positive and the other the negative current. The receiving apparatus consists of a relay and two bells of different tone, one on the right and the other on the left hand of the operator.

The relay has been already described; it completes a local circuit through the electro-magnets of one of the two electric bells, one of which corresponds to a positive, the other to a negative current. This system has obvious advantages as compared with the needle telegraph. The eye of the receiver is set free, and he can write the message as it is received as though from dictation; with this incidental advantage, that each word is heard, not as it is pronounced, but as it is spelt. It is found that from this cause messages are more correctly written down than when two men are employed, as with the needle telegraph, one to read the signals as he sees them, and the other to write from dictation: thus, one man not only does the work of two, but does it better.

Advantages are also claimed for this system over the ordinary Morse recording instruments; it is said to work more rapidly—that is to say, to transmit a greater number of words per minute. Forty words per minute have been accurately received, but in practice the clerks are ordered not to work at a greater speed than twenty words per minute. It is urged that there is at least as much chance of error in writing out the message from marks seen on paper, as from the sounds heard by the ear. It is also said that, from the employment of trains of wheels, the Morse recording telegraph does not admit of that facility of conversation, and rapidity of correction, peculiar to the needle and acoustic telegraph. Moreover, the acoustic telegraph is of itself an alarum. The only objection which can apparently be urged against it is the absence of all mechanical record of the messages received.

Telegraph companies can alone decide on the practical value of this objection. Sir W. O'Shaughnessy in 1861 reported that the substitution of an acoustic system for the Morse tape system effected a saving of about £3,000 per annum on the Indian lines, and was accompanied with twofold greater accuracy. The British and Irish Magnetic Telegraph Company are of opinion that the acoustic system saves them several thousands a-year in writers.

The States Railway Society, Vienna, M. (Austria, 666), exhibit an ingenious arrangement, by which batteries for transmission are required only at terminal stations, and, except for local purposes, are altogether dispensed with at intermediate stations.

Two equal and opposite batteries are constantly in connection with the line at the terminal stations; by depressing the key at either end, the clerk at that station removes his own battery from the line, and replaces it by a direct earth connection, which allows the far battery to work the distant terminal receiving instrument, and also the receiving instruments of all the intermediate stations. The keys of the intermediate stations, when depressed, remove their own receiving instrument from the circuit, and put an earth connection to both sides of the line through two sets of resistance coils of such length, that the currents produced by the two batteries, which work all the other receiving instruments, are of very nearly the same strength as that produced from the one battery when a terminal key is depressed. This system has been in practical use for about two years, and is now applied on about four hundred miles of line, with sixty-three railway-stations, and seventeen Government stations; its application is to be still further extended. There are some obvious objections to the plan, but these are met by the facts that it has worked successfully, saving 60 per cent. in the cost of batteries, and that it is being rapidly extended to fresh lines. Those who require fuller details will find an excellent description of the instruments and connections in the "Notice on the objects sent to the London International Exhibition," published by the Austrian State Railway Company.

Digney Brothers, M. (France, 1,414), exhibit what may be called a portable station for military or other similar purposes. A box, 15 inches by 7 inches by 7¾ inches, contains a key, a direct working Morse ink receiver with paper rollers, &c., complete, a galvanoscope, and all the necessary connections. The battery is carried in another box; or one of Messrs. Siemens' magneto-keys, already described, may be used instead of a battery.

J. Leopolder, Vienna, H. M. (Austria, 657), exhibits a still more compact arrangement, in which every requisite for Morse-signalling except the battery, is contained in a box 12½ inches by 8½ inches by 3½ inches.

(To be continued.)

Bonelli's Telegraph Company.—We were sorry to learn that the aerial cable, erected across the Mersey by the Bonelli Telegraph Company, had been again damaged by the mast of a vessel, necessitating a suspension of the company's operations for several hours. The cable has, however, been repaired, and is now in working order.

STEERING SHIPS BY TELEGRAPH.

At the Royal United Service Institution, on the 4th inst., a highly interesting lecture was delivered by Lieutenant A. H. Gilmore, R.N., upon the application of electric telegraphy to the steering and general management of a man-of-war. The lecturer stated that it was now seven years since his late brother directed attention to the subject, and proposed an apparatus for the purpose to the Admiralty, which had then been tried with perfect success on board some vessels of small size. The same system has recently been accepted by the Admiralty, and is now in use, with certain improvements, on board the Resistance, the Hector, Prince Consort, Orlando, Orontes, and the Queen's yacht, the Victoria and Albert, having been first adopted in that ship on the occasion of her voyage to bring the Princess of Wales to England. The great value of a system of perfect communication throughout any ship must be evident, as it is from the want of this that so many accidents happen. Ships come into fatal collision in fogs and dark nights before it is possible to alter the course by word of command. The man at the look-out has first to give his signal, and this is taken up by the next man, and so the word is carried, often in a gale of wind, through several men to the steersman, who possibly gets an imperfect, or even a directly contrary order, while, if he gets the right one, it is often too late. Many hairbreadth escapes in this way are commonly to be heard related by seamen, and no doubt small craft are sometimes run down which might have been avoided had it been possible for the man at the helm to act with sufficient promptitude. The apparatus appears to be extremely simple, and it is only surprising, now that we are shown it, that it was not adopted long ago. There is in front of the wheel at which the helmsman is stationed, a neat stand, somewhat like a sun-dial stand, with an upright dial-plate, upon which works a hand or indicator, and this plate is made transparent at night by a lamp. When the ship is steering "steady," the hand is vertical, or at rest, by its own gravity chiefly, and points to the word "steady;" when the course is signalled to "port," or "starboard," the hand moves to the left or right hand, as required by the officer in command, who of course directs the key-handle upon a similar dial-plate before him. But by an ingenious contrivance a sharp-sounding gong is struck with every signal, so that the man's attention is called to the dial-plate before him. If he is ordered to steer so many spokes of the wheel to port or starboard, the officer gives three, or any other number of strokes upon his dial, and the gong sounds at the same time. If the order "hard down" or "hard up" helm is to be given, it is only necessary to repeat the strokes rapidly. Mr. Gilmore showed the apparatus in action, and it worked in the most exact and unmistakeable manner. For ships of war, and especially the cupola ships, it would seem to be quite an indispensable means of working them efficiently, as orders may be sent about the ship with accuracy under any circumstances, and with a rapidity quite impossible in the noise either of a storm or a battle. Mr. Gilmore purposes to have a kind of table with several dial-plates upon it, each of which is in communication with a certain part of the ship, as the fighting quarters, the engine-room, the cupolas, and so on; this would be placed in the captain's pilot-house on deck, and thus the necessary orders to fight the ship by manœuvring in any way, to the magazines and to the broadside guns, prepare to fire, to change or revolve cupolas for the other tack, and in case of attacking as a ram, to charge or to back off as needed. The immense advantages of all this need not be dwelt upon; but the lecturer pointed out especially that in modern warfare by steam it would be of great importance to be able to manœuvre the ship rapidly, and to fire instantaneously at a ship moving with high speed. The double screw propellers which are now coming into use would not, he thought, be fully available without this method of conveying orders instantaneously. As to the ease with which sailors would learn the meaning of the signals and the working of the system, Lieutenant Gilmore felt quite sure that there was less difficulty in this method of steering than in the old one of steering by the compass.

The Magnetic Telegraph Company have lately extended their wires from the railway-station to the Catholic-hall, Blackburn, and on the 9th instant the new office in the Catholic-hall was opened for public business. This office, from its central situation, will be a great boon, not only to the merchants and manufacturers, but also to the inhabitants generally of Blackburn, who are thus placed in immediate communication with nearly every town in the United Kingdom.

SUBMARINE TELEGRAPH COMPANY (LIMITED).

The ordinary half-yearly general meeting of the shareholders of this company was held at the London Tavern, on Friday, the 4th inst., Sir James Carmichael, Bart., in the chair.

The Secretary, having read the notice calling the meeting, the chairman proceeded to affix the seal of the company to the register of the shareholders. The report having been agreed to be taken as read,

The Chairman said that in moving the adoption of the report, he was happy to be able to announce a steady and satisfactory increase in the revenue of the company since their last half-yearly meeting, and that, as compared with the corresponding period of last year, they were earning more than £100 per week over their receipts at that period, and this in the face of the fact that two of their cables were inoperative, the Emden cable being under repair, and the Danish, being in the hands of the Austro-Germanic authorities, not being allowed to be worked; the directors had, however, received information from their agent at Berlin, that an arrangement would in all probability shortly be made by which they would be allowed to work the line for commercial purposes, without detriment to their interests with either of the governments. The charges for repairs during the past half-year had been unusually heavy, owing to the very tempestuous weather, and for the past six months a steamer had been constantly employed with repairs, so that it was considered that the directors now knew the worst that could happen, the cost of the repairs appearing in the accounts as £5,244, which included four miles of 6-wire cable, spliced on to the Ostend line. The Calais cable had also been repaired, after only an interruption of two days, whilst some of the repairs could not be accomplished under several months. He had to congratulate them that now they had a *bona fide* reserve fund of £4,000, in North-Eastern Railway Debentures, and that, if the meeting agreed to the accounts presented, it would shortly be increased to about £6,500. He had a melancholy topic to introduce to them, namely, the death of their most valued coadjutor, Mr. John Watkins Brett, and who, in fact, appropriately has been called by Professor Morse the father of submarine telegraphy, and who had been of eminent service to the company, for whenever an emergency arose, he was always ready to give his time and money to get through it. With regard to the extension of telegraphy, he might remark that in 1845 Mr. Brett made a proposal to the Belgian government to connect Belgium with this country by a submarine cable, but the proposal was laughed at. Since then, however, submarine telegraphy had proceeded so rapidly, that he hoped next year would witness the union of America with this country, by means of the Atlantic cable, which would just be twenty years since Mr. Brett's first proposal was made with regard to Belgium. He must now refer to another loss the company had sustained by the resignation of their late secretary, Mr. Courtenay, whose courteous behaviour to every member of the company had gained him the esteem of all, whilst it was with much pleasure that he bore testimony to the zeal and ability with which he discharged his duties. Mr. Courtenay had accepted an appointment in connection with the Indian government, but the directors had been fortunate in securing the services of Mr. Clare, the accountant to the company, who would discharge the duties of both offices. At a meeting of the shareholders, in 1859, a vote was taken, by which the remuneration of the directors was raised to £1,000 per annum, but it was afterwards found that, on account of the meeting not being made special, and no notice being given, the vote was illegal. The amount was then reduced to the original allowance of £400, but, as they were desirous of strengthening their Board, by the addition of two gentlemen of high standing in society, they would require something to offer them for their services, they should, therefore, at the proper time, have to ask them to increase the annual allowance to the directors. He had now only to move that the report, with the statement of accounts, be received and adopted.

Mr. Hindmarsh seconded the motion.

Rev. W. Horton wished to know whether any damages had been recovered on account of the injury done to the Dover and Calais cable by the Swedish vessel.

The Solicitor, in reply, said that the point had been brought before the Law Courts, and it was contended that the company had no right to lay their cables at the bottom of the sea, and that they could not recover for any damage done to them; it was, however, now legally decided by the judges that they had a right to lay their cables, and that they could recover for wilful damage done. The next point which must yet be decided by a jury, was whether the cable was maliciously injured; that, however, remains open for the present.

The Chairman said that the damage done would amount to about £1,000, that the owners of the vessel were large and highly respectable gentlemen in Sweden, and connected with a house of business in London; consequently, should the case come before a jury and a verdict obtained, there would be no fear about obtaining payment; but the trial had taken place more for the purpose of establishing their right to lay their cables at the bottom of the sea, and that was now decided.

Rev. W. Horton said that his chief reason for asking the question was to bring out the decision which had been arrived at. He thought it very important that it should be known that the question had been authoritatively settled, that those persons who injured the cables were amenable to the owners thereof for the damage done. There was a little discrepancy in the accounts, which, he had no doubt, might be readily explained, but which did not appear just then clear to him. In the joint balance sheet he found the amount of reserve fund, on June 30th, 1863, stated to be £3,922 18s. 10d., whereas, by reference to the balance-sheet, on the 31st December, 1862, he found £1,219 15s., and on the 30th June, 1863, £2,214 8s. 3d., making it altogether £3,434 3s. 3d., and not £3,922 18s. as stated in the accounts. He should like to have that matter explained.

The Secretary stated that at the moment he could not give the explanation, but if the proprietor would call at the office, he would show him the books, and make it quite clear.*

Mr. Braithwaite remarked that an important question with a submarine company was the maintenance of the cables in a state of efficiency, he should, therefore, like to know whether they saw their way clear to reckon upon any specific amount as the cost of repairs during the year; these amounts appeared to vary constantly, and until they could arrive at something like an average for repairs, they could not tell how to reckon upon the cost of working.

The Chairman considered it impossible to make a calculation. They had had as severe a trial during the past year as he thought they could well have, and should reckon that £8,000 a year would keep their cables in proper order. He had never found any firm or company willing to contract for the repairs of the cables, and he did not think that any would undertake it. All the repairs which had been done had been paid out of the revenue.

The motion for the adoption of the report having been put to the meeting, was carried unanimously.

The Chairman then moved, "that in accordance with the recommendation of the court of directors, a dividend for the half-year ending 31st December, 1863, at the rate of 4 per cent. per annum (less income-tax) upon the capital of the company be declared, and that it become payable on and after the 12th day of March next," which having been seconded by Mr. Maxwell, was carried unanimously.

The Chairman next moved, "that the Right Hon. James Stuart Wortley be one of the directors of the company."

Mr. Braithwaite, in seconding the motion, remarked that it was very obvious that every year increased the importance of electric telegraphic communication, and such had been the increase during the past year that it showed the necessity of their having gentlemen on the board of directors whose position in society would enable them to command that consideration for the company which its importance demanded. Mr. Wortley was chairman of the Atlantic Telegraph Company, and held a high position in the country, and he was glad to find his name proposed to be added to their board, for it was most desirable that they should have as large an amount of influence as possible, seeing that it was probable that the globe would eventually be encircled with wire.

Mr. Reid said that he considered that the board was large enough already. There were six on the board, besides the chairman, and he thought that sufficient. He thought that it would be better if the consideration of that question was deferred until the dividend was larger. He should like to know the amount of holding which both Mr. Wortley and Mr. Moor had in the company? (The Chairman: £1,000 each.) He should prefer good business men to members of Parliament, for he considered that they had enough to do in other ways. He merely threw this out as a suggestion, and not for the purpose of causing division.

The motion having been put from the chair, was carried unanimously.

The Chairman next proposed, "that Mr. Moor, M.P., be one of the directors of the company," which having been seconded by Mr. Scamell, was also carried unanimously.

Mr. Braithwaite said that he had now to propose, "that the yearly allowance to the directors be £1,000." He thought that the time was now come when they should increase the amount to be allowed to the board for managing the affairs of their company. They had now turned the corner in their financial affairs, and he thought that they ought to accede to this proposition. It was only those who were acquainted with the working of the company that knew the laborious duties of the directors, and he therefore hoped that no objection would be made to the motion he had now proposed.

Mr. Chatfield seconded the motion.

In reply to a question,

The Chairman said that £360 per annum was allowed for the management of the French company, of which there were three directors; so that the total allowance for the expenses of direction, if the motion was agreed to, would be £1,360.

The Rev. W. Horton felt pleased that the accounts of the company were such as to justify them in increasing the remuneration of their directors, and he thought that, by agreeing to this proposition, they should be expressing what they were bound to express, namely, their sense of obligation to the directors for the way in which they had conducted the affairs of their company, and their confidence in the fidelity of their management in the future.

The motion was carried unanimously.

The thanks of the meeting having been voted to the chairman and the board of directors, the meeting separated.

* The Secretary explains this by stating that £488 15s 7d., the amount of reserve fund belonging to the French company, on 30th June, 1863, is included in the amount of £3,922 18s. 10d., which sum is shown to the credit of the reserve fund in the annual BALANCE-SHEET presented on this occasion.

TELEGRAPH CLERKS' PROVIDENT FUND.

THE first half-yearly meeting of this society took place on Tuesday evening, at the offices of the London District Telegraph Company, 90, Cannon-street, E.C.; G. Sheward, Esq., presided. The room was crowded with members of the society.

Letters having been read from the Honourable A. Kinnaird, and others, expressing their regret at not being able to attend, the Secretary announced that Mr. Alderman Salomon, M.P., had liberally sent in a donation of £5 5s. towards the fund.

The SECRETARY read the report, from which it appeared that the progress of the fund was most encouraging and satisfactory, the committee having been enabled to invest £184 2s. in the purchase of Three per Cent. Consols to the value of £200. The annual subscriptions amounted to £55 12s. 6d., although the fund had only been in operation since October last, and it now numbered seventy-one members, composed entirely of the clerks and employés of the different telegraph companies. The claims, up to the present time, were limited to two, which were both on the sick fund. Dr. Cousins, 49, Camden-road-villas, has consented to become honorary physician to the fund. Dr. Peplow, 111, Great Russell-street, Bloomsbury, has been elected medical officer of the fund. Dr. Sutro, of Finsbury-square, had consented to act as consulting physician, and, through his introduction, Messrs. Baumgarten, of 113, Leadenhall-street, had undertaken to prepare his prescriptions for any member of the fund at cost price.

The CHAIRMAN, in moving the adoption of the report, explained the advantages attendant on joining the society, and entered at some length into explanations of a string of questions which had been addressed to him by one of the members.

The motion for the adoption of the report and the balance-sheet having been seconded, was carried unanimously.

The officers were then re-elected, and a vote of thanks accorded to the chairman for presiding on the occasion.

Mr. SHEWARD, in returning thanks, congratulated those present on the fact of the Princess of Wales having become a patroness of a society composed of so many of her own sex, and said the thanks of the meeting were due to her Royal Highness for the very liberal donation which she had forwarded.

The proceedings then terminated.

CORRESPONDENCE.

ATLANTIC TELEGRAPH CABLE.

To the Editor of the TELEGRAPHIC JOURNAL.

SIR,—Will you, or any of your correspondents, kindly answer the following queries in the next number of your valuable journal:—

1st. In what stage of construction is the Atlantic Telegraph Cable; when is it likely to be finished? 2. About what time is it likely to be laid, and its probable landing place? 3. What instruments are likely to be used in working that cable; whether the Morse code?

A CURIOUS SUBSCRIBER.

[The manufacture of the Atlantic cable has not yet been commenced, but we are informed that there is every prospect of its being completed, and ready for submergence, in May, 1865. At present it is understood that the termini will be Valencia, in Ireland, and New Perlican, Trinity Bay, St. John's, Newfoundland—a point which has been found to possess many advantages over the late station at Bull Arm. The instruments to be used for transmission have not been decided upon, but we believe that every effort will be made to ensure the employment of those instruments which are found to be best suited to this description of work.—ED. T. J.]

THE RELAY.

To the Editor of the TELEGRAPHIC JOURNAL.

SIR,—Mr. Fleeming Jenkin, in his report on the various instruments at the International Exhibition of 1862, gives a very interesting account of the different forms of *Relays* which are in use in various countries. The following quotation describes the first relay patented by Messrs. Cooke & Wheatstone, in 1836-7:—"In the improvement for sounding alarums in distant places by the aid of an additional voltaic battery, which is brought into action when required for sounding the alarum, the sounding thereof being either by direct application of the attractive force of occasional magnetism, or by applying such force to let off clockwork alarums, the requisite occasional magnetism is excited by an electric current derived from that additional battery, the metallic circuit by which that current is so derived from the said battery being formed (when the same is required to act) by an angular motion then communicated to a magnetic needle, which is disposed within multiplying coils of conducting wire, through which an electric current is transmitted from a distance, the angular motion of the needle being caused to make the requisite contacts for forming the metallic circuit of the additional or alarum battery."—Yours, &c., TULE.

CURIOSITIES IN SUBMARINE TELEGRAPHY.

To the Editor of the TELEGRAPHIC JOURNAL.

SIR,—In August and September last year, it was announced that the amount of capital the Atlantic Telegraph Company required had been subscribed, and that—at the *unanimous* recommendation of a scientific committee, consisting of Captain Galton, R.E., Mr. Fairbairn, Professors Wheatstone and Thomson, and Mr. Whitworth—the tender of Messrs. Glass, Elliot & Co. had been accepted; and also that *the* cable was then and there being manufactured, the contractors being bound by their contrac to make and submerge the same, and hand it over to the company, in complete working order, in the summer of 1864.

We are now in March, 1864, and what do we find? That although the contractors and their friends may have become liable for 20 per cent. of the capital, that there is nevertheless such a deficiency as to checkmate all procedure—so that there is not now an inch of the cable being or yet made. The type of cable thus scientifically selected—the same as the Algiers cable—is a curious and paradoxical fact, when we refer to the report of Captain Galton and Mr. Fairbairn, when acting on the Government Commission, whilst, also, the two Professors, as Jurors to the Exhibition of 1862, make the following statement as to that particular form of cable:—"This form of cable would deserve a much fuller description than is here given, were it not for the fact, that it probably will not again be used." "The toredo consumes the hemp with great rapidity, leaving a mere bundle of loose wires round the core, which cannot then be lifted for repairs."

Besides these curiosities, it is well to bear in mind that this selection of cable is come at after years of dear-bought experience, and abundance of facts, which go to show that out of upwards of 15,000 miles of cable submerged, first and last, there are not now, at this moment of time, 2,000 miles of telegraphic lines of communication in effective working order, or any in deep water—whilst a moiety of these are multiple wire cables, differing in their mechanical construction from the peculiarly-successful single-wire conformation selected by the scientific committee for the depths of the Atlantic.

Experience teaches! Can anyone wonder that the public feel shy to join in ventures, however great and grand, when so administered? And how do the results tally with the chairman's statements at the public meeting held in Liverpool last spring?

March 8, 1864. MAGNA EST VERITAS ET PREVALABIT.

[Our correspondent is erroneously impressed as to the present position of the company.—ED. T. J.]

TELEGRAPHING WITHOUT WIRES.

To the Editor of the TELEGRAPHIC JOURNAL.

SIR,—Would you be kind enough to inform me, through the columns of your journal, whether a patent was not taken out a year or two ago for telegraphing between different places, without wires—and if so, if the same has been practically applied?

If not troubling you too much, perhaps you could further inform me as to the nature of the apparatus and the electricity employed.

I am, sir, yours,

Southport, March 8, 1864. A READER.

[Mr. Haworth has patented a system of telegraphing without wires. We insert an extract from Mr. Haworth's specification, filed on the 26th Sept., 1862. We were not present at the experiments.—"The size and power of the battery will depend, in some degree, upon circumstances—such as the distance to which it is intended to convey the message, the strength and direction of the earth's currents, and even the state of the weather, more power being required in dry than in damp weather. These points must be taken into consideration, and allowance made for them. For a distance of ten miles from Notting-hill, Bayswater, Middlesex, to Croydon, in Surrey, I have found a Smee's battery of two cells at each end, containing plates three by five inches, to suffice. For about 50 miles, from Notting-hill, Bayswater, to Brighton, in Sussex, I have used, with success, a Smee's battery of three cells at Notting-hill, and the same number at Brighton. For 200 miles from Notting-hill, to Bangor, in Wales, I have required six cells, with plates of the size above named. I have found that less power is generally required to convey a message from north to south and from south to north, than from east to west, or from west to east." Haworth's last patent was taken out a few weeks ago, and so soon as the specification is published, it will be inserted in this journal. Mr. Haworth is, we believe, abroad at the present time.—ED. T. J.]

TELEGRAPHIC FEATS.

To the Editor of the TELEGRAPHIC JOURNAL.

SIR,—In your impression of March 5th an "Old Double Needle and Morse Clerk" says, "A Morse-sending clerk can be instantly arrested." If not trespassing too much on your space, I should feel obliged if he would say how this is effected?

I am, sir, yours, &c.,

March 8th, 1864. D. W.

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—Although I think no real benefit can result from the controversy as to the respective merits of different systems of telegraphy, I think the letters appearing in your issue of this day call for a reply. Anyone connected with telegraphy is well aware of the fact that, as a general rule, telegraphists are prejudiced in favour of the instrument they are accustomed to work; and in reading their opinions, allowance must be made for this.

"Fairplay" and "Bon Accord" seem to be relating the same feat as to the transmission of the Queen's Speech, and I cannot reconcile the difference of their statements, one giving the rate of speed as twenty-seven and the other as thirty words per minute.

From several years' experience of telegraphy in the Magnetic Company, and an acquaintance with the Morse and electric instruments, I cannot believe that, with the instruments employed by the Electric Company, a speed of thirty words per minute could be maintained, although it might be obtained for one or two minutes.

Of course a great speed can be attained for a few minutes—as an instance of which, *one hundred and three words* were transmitted to Manchester, and written down there by a clerk from bells in two minutes.

Your correspondent "W.H.N." states fifteen words per minute as the rate of the single needle (electric) instrument; and in stating this, I do not think your correspondent referred to the Morse, but to the old single needle instrument of the Electric Company, the speed of which is about the rate mentioned by your correspondent. He further says, referring to the Morse instrument, "A yarn must be finished before the sender can be stopped."

This is contradicted by your Dover correspondent, who is doubtless in the service of the Submarine Company, and is unaware of the fact that on some (if not all) of the electric Morse instruments, the receiving station cannot stop the sender until he has finished sending.

Your Dover correspondent alleges that bad writing (I presume on Morse slip) may be deciphered if carefully scrutinised, whilst on bells it must be repeated. I cannot see any advantage in time would be gained by the "scrutiniser" over the "repeater."

Another Dover correspondent alleged that the Morse instrument is superior to the bell instrument for the transmission of messages in foreign languages. Such a statement could only be made by one who is either strongly prejudiced in favour of the Morse system, or who is unacquainted with the working of any other system.

Any advantage obtained by the Morse instrument would be merely from the fact, that in general the clerks attending foreign circuits are acquainted with foreign languages—an advantage the clerk attending home circuits does not usually possess; but even with this advantage, I doubt the superiority of the Morse instrument, for I can instance *one hundred* messages for the continent being received from bells by a London clerk from Liverpool in one hour and fifty-five minutes, the majority of which were in foreign languages, and the whole of them were counted and timed by the receiver. I do not think this could be *equalled* by any Morse clerk.

No one unacquainted with the bell instruments can possibly appreciate their great value and utility.

With regard to the assertion, that the magnetic instrument is unsuited for long circuits, I do not think a much longer circuit is worked by the Morse instrument than one completed by the magnetic, viz., London to Queenstown and Valentia, *viâ* Cambridge, Doncaster, Liverpool, Stranraer, Belfast, Dublin, &c. Trusting you will find room for this in your valuable journal,—I remain, sir, yours obediently,

J. H. HARPER.

London, March 5, 1864.

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—The discussion which has been going on in your columns for the last few weeks, as to the relative merits of the several signalling instruments, has been deeply interesting to me, as it has, I have no doubt, been to all telegraph clerks. Notwithstanding all that has been said *pro* and *con*, I hardly think a single convert will have been made by either side, for all expert clerks (the best judges) have what I may call an affection for the instrument with which they are most efficient. I wish to speak impartially, and can fully recognise the great benefits which the Morse instrument possesses in that it records whatever is sent, which for reference must necessarily be of great value; but does this virtue counterbalance the difference in speed which exists between the Morse and bell instruments? Taking the authority of your Dover correspondent (in February 20th) thirty words per minute seems to be a good performance for the former, whereas the bell instrument is capable of doing forty-five of the same matter—*i.e.* the bell instrument would transmit three columns of a speech while the Morse was doing two. This is a great difference in speed, and I do not think the recording faculty of the Morse compensates for it. Morse clerks will be loth to allow that their instrument is surpassed in speed by the bell instrument, but I beg to remind them that all the signals transmitted by the keys of the magnetic instrument are dots, and must of necessity occupy less time than when copiously interspersed with bars, as in the case of the Morse, both keys having a downward motion. It seems to be inferred by many of your correspondents that the bell instrument is not a correct one; probably they arrive at this conclusion from their own acquaintance with unrecording instruments; but I can assert from experience that in this respect there is no comparison between a needle and a bell instrument, the ear being a much surer mode of communication than the eye. If this discussion has no other effect, it will have given prominence to the capabilities of an instrument which, until now, has not received a due appreciation of its merits.—Yours obediently,

Bradford, Yorkshire, March 8th, 1864. MAGNETO.

THE TELEGRAPH CLERKS' PROVIDENT FUND.

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—In reply to Mr. Newbury's letter, in your last week's journal, I must observe that the denouncement of his meeting was too severe against the newly-established Telegraph Provident Fund, of which that excellent and benevolent lady, Miss Oppenheim, is the secretary.

I do not come forward here to dispute what has been said, but merely to observe, that although in most cases the assertions were true, the deductions from them were harsh, as the following statement may show.

In round calculation the sum of 3d. per week is demanded (not a very exorbitant amount), for which trifling payment we receive, in cases of illness, a weekly allowance of 10s., and in that of temporary disorder the best medical advice from a physician, together with assistance from the Fund. No doubt this society, as with most others in their commencement, must ere long undergo some modification; but looking at the fact—and one which my own experience can prove—that telegraphic employés are invariably of a sickly temperament, it ought not to be grudged that some benefits should fall to the other side; and notwithstanding the society's late formation its sick list is already large, and much greater than was at first anticipated.

It is always easier to condemn than praise, and still more so to do evil than render good; but, sir, when we consider such management as the board is composed of, when such names stand forward as Mr. Samuel Gurney, Sir Morton Peto, and others of gentler form as the patronesses, whose very names echo virtue and munificence, only give time to the undertaking, and little will be the fear of the result.—Yours, &c.,

GEORGE BENSON.

Submarine Telegraph Company, 58, Threadneedle-street, E.C., March 9, 1864.

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—I am glad that Mr. Newbury has so fully explained the reasons why he and his friends are not satisfied with the rules and regulations of the above Fund, as it affords a fair opportunity of discussing the matter in your columns, the result of which I trust will be to remove the unfavourable impressions from your correspondent's mind and others for whose benefit the Fund has been established. I believe that the production of certificates of birth or baptism, &c. are indispensable before being admitted as members into any of our well managed and regulated provident institutions. No insurance on life can be effected in any office without such certificates, as well as those of the medical officers appointed to examine as to the applicant's state of health, &c. I think that such requirements and precautions should not be considered as likely to exclude the clerks and others employed under telegraph companies from becoming members.

Rule 2, which renders it incumbent on the part of the patients to "find their own bottles, &c.," and to attend at the houses of their respective surgeons before ten o'clock in the morning, might be with advantage modified or, indeed, expunged altogether.

When the members of the Fund are so widely dispersed over the country it is essential that certificates for claiming sick pay should be signed by either the minister of the parish or some other responsible person in the town in which the applicant resides; the absence of such a precaution might lead to irregularities.

Rule 9th certainly should be modified. It is absurd to attempt to debar the male members from enjoying the healthy and invigorating recreations, such as cricket, the racket, or the exercise of the gymnasium, or to prohibit the female members from joining in the merry dance, &c.

With the above exceptions I do not think that the rules are in any way oppressive, by requiring of the members to go through humiliating formulas, &c., and I hope that Mr. Newbury and his friends will lend their co-operation to carry out the object of the institution, bearing in mind that in union there is strength, and that by the exercise of a little forbearance towards those who have had to toil and labour against much discouragement and apathy, and who are anxious to extend to telegraph employés the advantages of a Provident Institution on a permanent and secure foundation, the wishes of himself and others will meet the consideration to which they are justly entitled.

In conclusion, I do trust that the institution will be the means of removing what I still must characterise the senseless prejudice and rivalry which have too long existed between those employed under our various companies.—Yours, &c.,

March 8, 1864 A SHAREHOLDER.

To the Editor of the TELEGRAPHIC JOURNAL.

SIR,—I am glad Mr. Newbury has furnished us with the reasons of his disapproval of the Provident Fund. Judging from the long list, a careless observer would naturally infer that the society has been hastily bungled together, without a thought as to the welfare of the parties to be benefited; but a moment's consideration will convince the reader that the majority of the Magnetic objections are puerile in the extreme. We must, however, give our friends of Threadneedle-street their due meed of praise for the gallantry with which they take up cudgels on behalf of the fair sex, and do battle for the weaker vessels. Mr. Newbury and his confrères grow virtuously indignant when they learn that female members will not derive sick pay and medical attendance when visited by the illness accompanying maternity. I have not expressed myself with that grace, ease, and pathos which the self-imposed champion of our oppressed and suffering sisterhood revelled in when he condemned the shortcomings of the fund in this respect. At present I believe there is no member of the society in immediate want of this relief, and when the necessity begins to be felt means, I have no doubt, will be found to meet it, in the formation of a special subscription for these "happy events." It would be a manifest injustice to the male subscribers to allow this relief to come from the general fund. Mr. Newbury assumes that the rule referring to accidents, &c., attending sports and games, is injudicious. I can easily explain this, by mentioning that by some clerical error the word "unlawful" has been omitted before sports. But the grand point of objection is the "technicalities!" How unfortunate it would be to wound the tender susceptibilities of a would-be young mamma by quoting her correct age, and how unpleasant to reveal the melancholy fact that your father is older than he was twenty years ago. Baptismal certificates are not insisted upon unless some reasonable doubt is entertained of a candidate's statement of age. I think our friends of the Magnetic would show themselves to greater advantage if they had come forward to lend a helping-hand to those who are endeavouring to benefit them, instead of holding themselves aloof, and unfairly criticising what has been done for the mutual benefit. I quite agree with "A Shareholder" upon the rivalry existing between the various services. In the case of the Fund, it is to be lamented that it did not take rise in Threadneedle-street, or owe its origin to Lothbury. Some such idea as this inspired Mr. Newbury when he referred to its "soi-disant" connection with the District Telegraph Company. Neither of the services possess any official influence over the society. The District Company has, indeed, come forward with great liberality, which contrasts very favourably with the spirit manifested by larger and wealthier telegraph communities. I am led to hope that, after a while, the fund will be independent of these extraneous means of support, and will depend entirely upon itself. This will not be the case for some time to come. In the meanwhile I would earnestly appeal to my fellow-employés to advance, by every means in their power, the moral, social, and general prosperity of the telegraph clerk.

ONE OF THE LEAST.

London, March 9, 1864.

[We had a letter from "One of the Least" in type last week, but owing to press of matter it was excluded; at the request of our correspondent, it has been cancelled, and the foregoing published in lieu thereof.—ED. T. J.]

TELEGRAPHIC NEWS.

THE ATLANTIC TELEGRAPH COMPANY.—A vacancy has occurred in the direction of this company by the demise of Sir Wm. Brown, Bart., of Liverpool.

THE GREAT EASTERN STEAMSHIP.—In anticipation of the contract for manufacturing and submerging the Atlantic cable, the eminent firm of Messrs. Glass, Elliot, & Co. have secured the Great Eastern for the latter purpose. This vessel has many advantages over ordinary ships, as from her great length there is an entire absence of pitching, and as the magnitude of her hold will admit of the whole of the cable being paid out into the ocean at one length.

GISBORNE'S MECHANICAL SHIP STEERING APPARATUS.—In one of our early numbers we gave a description of a very ingenious apparatus, the invention of Mr. F. N. Gisborne, for steering vessels by the aid of electricity. We have had an opportunity of examining an exceedingly efficient apparatus, contrived by Mr. Gisborne for the same purpose, by mechanical means, which we intend fully to describe in a future number. The apparatus is to be seen at Mr. Gisborne's office, Adelaide-place, London-bridge.

THE ATLANTIC TELEGRAPH.—In 1862, Captain Orlebar, of the U.S. navy was employed to make a survey of Trinity Bay, Newfoundland, for the purpose of ascertaining whether there was not a more suitable landing place for the Atlantic cable than Bull Arm. From his report we learn that at New Perlican there exists a deep channel, which will form an excellent bed for a telegraph cable; that the adoption of this place for a terminus would enable the Company to effect a saving of 40 miles of cable, besides placing the line in immediate communication with New York and the interior of the American continent. Captain Hoskin, R.N., has also been engaged in a survey of the Irish coast, and his report confirms the previous selection of Valentia, in the south of Ireland, as the most eligible station for the Atlantic telegraph. It is pretty generally understood that these recommendations will be acted upon, and that the cable will be submerged in the summer of 1865.

ELECTRICITY AND WARFARE.—Experiments are being made, in the evening, at the Danish head-quarters, with electric light, with a view to apply it to warlike purposes, to watch the enemy's movements in the night, and to enable the artillery of the forts to fire in the darkest weather. With what practical results such contrivances are attended we shall soon learn.

QUEENSLAND'S TELEGRAPH.—Amongst the public works in the above colony, the chief and most important is the construction of the first railway, and after that, but hardly inferior in interest, is the proposition for the extension of telegraphic communication to the northern parts, with the view of making the wire available ultimately as a link of the proposed Anglo-Indo and Australian line. For this purpose a sum of £85,500 has been granted by the legislature.

THE PERSIAN GULF TELEGRAPH.—By advices from Bombay to the 14th ult., we learn that the first section of the Persian Gulf telegraph cable, 359 miles in length, from Gwadur in Beloochistan to Cape Mussendom on the Arabian coast, has been successfully laid from the ships Kirkham and Marian Moore. Colonel Stewart and Sir Charles Bright arrived off Cape Mussendom at noon on the 9th instant, and their telegram through the cable announcing the completion of the work thus far reached Bombay at three p.m. the same day. Dr. Esselbach, superintendent of the Mekran telegraph, who accompanied Colonel Stewart, committed suicide by throwing himself overboard at sea in a fit of nervous excitement. From the *Bombay Gazette* we learn that the Tweed, which is the third of the cable ships, has arrived, and is only waiting for the Ferose, now overdue, to be towed up the Gulf, when the laying of the second section, from Cape Mussendom to Bushire, will be at once commenced. The Assaye, with the third section on board, left England nearly four months ago, and anchored in our port yesterday; and the probabilities are, that by the end of March the whole length of the cable will have been submerged, and that Bombay will be in direct telegraphic communication with Bussora. Recent letters from Bagdad, however, make us anxious for the safety of the short land line from Bussora to that city, the Arabs having already, as we learn, broken the wires and ill-treated the workmen engaged in the construction of the line. Another difficulty likely to make itself felt when the cable has been laid down is the inefficiency of the present telegraph from Kurrachee to Bombay. It will be most vexatious if, after so many more serious obstacles have been successfully overcome, telegraphic communication with England is interrupted precisely where it ought to be most safe and regular. The Arabs between Bagdad and Bussora may be quieted partly by threats and partly by bribery, but the Indian telegraph department can neither be frightened nor coaxed into doing its work properly, and the sole remedy is for an independent English company to make a line of its own between Bombay and Kurrachee. A portion of the above information appeared in a second edition of this journal last week.

PARLIAMENTARY NEWS.

GOVERNMENT TELEGRAMS.

Mr. D. GRIFFITH asked whether a despatch from Earl Russell to Lord Bloomfield, at Vienna, of the 18th of January, 1864, to which an answer was returned by Lord Bloomfield, of the date of the 19th of January, from Vienna, printed among the Danish papers, was sent by telegraph from this country: and whether the Secretary of State for Foreign Affairs would have any objection to direct that in future dispatches sent by telegraph should be distinguished from those sent by the ordinary means of communication, in order that the dates of dispatches might correspond with the facts of their transmission and answers, and be at once intelligible to members of the house without further explanation.

Mr. LAYARD regretted he was unable to explain himself clearly to the hon. member the other evening. He would, however, again endeavour to do so. Those dispatches which were published were not sent by telegraph, but they were founded upon short telegrams sent in cypher. Each telegram was afterwards extended into a full dispatch, in order that the house might have the whole matter before them. For the very obvious reasons that telegraphic messages must be very short, they could not be produced literally in their original cipher. Care was, however, taken, when acknowledging a dispatch, to state whether it was telegraphic or not. The hon. gentleman would find from the answer whether the original dispatch was sent by telegraph or not. If, for example, it was considered necessary to send a dispatch from London to St. Petersburgh, with the view of receiving an answer on the same day or the day afterwards, it was evident that it should be sent by telegraph.

Mr. D. GRIFFITH complained with warmth that the hon. gentleman had not answered his question. He had given him notice of his question, which he wished to be answered by his chief, and he presumed that the hon. gentleman would have come there to answer it on behalf of his chief (hear, and laughter).

Mr. LAYARD said he really did not know what answer he could give to the hon. gentleman. It seemed to be quite impossible for him (Mr. Layard) to make the hon. gentleman understand. In the very dispatch to which the hon. gentleman alluded, the answer stated that it was a telegraphic dispatch. It would be an insult to the sense of the house to explain that a dispatch sent to St. Petersburgh, which was replied to on the same day or the day afterwards, must have been sent by telegraph (hear, hear).

MISCELLANEA.

MR. HORACE JONES, who has recently been elected City Architect, in the place of the late Mr. Bunning, designed the Magnetic and Submarine Company's Central Station, at 58, Threadneedle-street.

LATELY a Belgian author proposed that the guillotine should be replaced by the electric discharge. "Fancy the criminal," says he "standing on the scaffold addressing the multitude. The hand of justice lowers itself upon his head, the electric spark flashes and cuts him short. . . . Death, which we fear so much, is only *the pain multiplied by the time,* and electricity, travelling some two hundred and forty thousand miles per second, whilst the biggest criminal rarely exceed two yards, the passage from life to death would be accomplished in about the one million four hundred thousandth part of a second!"

GLASGOW CONTROLLED BY ELECTRICITY.—We have to call the attention of the public to the clock controlled by a current of electricity, from the observatory of the Glasgow University, which is to be seen in one of the windows of the establishment of Mr. Nunhead, clockmaker, Buchanan-street. This interesting and beautiful specimen of the application of scientific result, to the useful purposes of life, is furnished with a conspicuous dial, about three feet in diameter, upon which revolve hour, minute, and second hands, enabling the passer-by to ascertain Greenwich mean time, at any hour of the day, with the utmost possible precision. The pendulum terminates on a coil of wire, and as it swings to one side and the other the coil alternately envelopes and discloses two permanent bar magnets, which may be seen underneath. As the pendulum of the standard clock at the observatory vibrates to and fro, it presses slightly against a spring, which causes the current of electricity to flow from the battery at the observatory along the connecting wire coil of the pendulum, which becomes from this cause an electro-magnet for a short time during each successive second, and the mutual action existing between this temporary magnet and the permanent magnets which it embraces, and the course of its oscillations constitutes a controlling influence by which the pendulum of the distant clock is made to vibrate in perfect unison with the pendulum of the standard clock at the observatory. We hope ere long to see several of these useful apparatus established, for the public benefit, in different parts of the city.—*Glasgow Daily Herald.* [The good citizens of Glasgow seem to have forgotten that a similar clock was erected in the town many years ago by their ingenious countryman, Mr. Alexander Bain.—ED. T. J.]

THE ROYAL INSURANCE COMPANY.—On Thursday, the 11th of February, George Edward Taunton (on behalf of some of the shareholders) obtained an injunction to restrain the directors of the Royal Insurance Company "from paying or making good any loss or damage occasioned by the burning of the vessel *Lotty Sleigh,* or the explosion or concussion thereby produced, upon or in respect of any policy or insurance granted by them against loss or damage by fire, and from allowing or paying, or causing to be allowed or paid out of the funds of the said company any claims arising from such loss or damage aforesaid." The case came on for hearing on the 29th February, and appeared to create a deal of public interest, and as the decision of Vice-Chancellor Sir Page Wood is important, not only to the directors of large companies, but to the public generally, we quote the following remarks from the summing-up:—"This is a case of considerable importance in reference to the management of all societies of a joint-stock character. The court has been always careful to prevent the application of the moneys of the shareholders who contribute to these enterprises—to prevent the funds being applied to any purpose other than that which is legitimately the purpose and object of the association. On the other hand, it is not for the benefit of the shareholders that the legitimate business of the association should be in any way impeded by narrowing the powers of the board of directors, in such a manner as to prevent the board from carrying the objects of these great associations into full and complete activity, according to the best modes that may present themselves to the minds of the directors, and which are within the ordinary course of business. It is not a case of applying the funds to purposes ultra the purposes and objects of the association, but the purpose to which the directors have applied the funds is, undoubtedly, whether rightly or wrongly, for the purpose of securing to the company the best profits that they think can be secured by their mode of conducting the business."

THE discoveries of Franklin displayed the influence of electricity in the production of the most magnificent phenomena of nature. That of Volta has led to the development of its connection with her more silent but important processes. Like the power of gravitation, it seems to apply more extensively the farther its investigation is pursued. Like that power, too, its nature may for ever escape our cognizance; but the contemplation of its effects may supply new facts calculated to extend the resources of art, and enlighten our conception of the infinite variety and harmony of natural phenomena. Such pursuits are amongst the best sources of intellectual improvement, for they call into action the highest powers of the mind, and present a constant succession of interesting objects for their exercise.

ON the occasion of the opening of the telegraph line between Cape Town and Graham's Town, the press of the latter telegraphed the following distich to that of the former:—

"Good Lord, what fools ye be,
To send such message up to *we.*

N.B.—The right of translation is reserved by the authors."

TELEGRAPHIC FAC-SIMILES.—A correspondent has furnished us with an account of experiments made in April, 1848, which we insert:—A trial was made, between London and Brighton, of Mr. Bakewell's copying telegraph, to test whether distance would interfere with its powers of transmitting copies of writings. An instrument at the central office of the Electric Telegraph, in London, was placed in connexion with a corresponding instrument at the York Hotel, Brighton, and a communication in writing was opened between those stations. Several messages, the *fac-similes* of the writing applied to the instrument in Brighton, were received in Lothbury, in the presence of gentlemen connected with the telegraph company. The writing formed by electro-chemical decomposition could be distinctly read, and the signatures could be recognised. The rapidity with which the transmission was effected was about 150 letters per minute, and a much greater speed is said to be attained when the instruments are in regular work. The messages were written in full, with capitals and points, but abbreviations and even short-hand symbols, might, it is stated, be used. In addition to the authentication of communications by the signatures of correspondents, and the avoidance of errors by the transmission of *fac-similes* of the original messages, this telegraph is regarded as possessing peculiar means of maintaining secresy. Some of the communications from Brighton to London on Thursday were impressed invisibly on the paper, so that no trace of writing could be seen until the messages were washed over with a chemical solution, when they became visible.

THE REPORTS OF TELEGRAPH COMPANIES.

IT is always gratifying to the Directors of Joint Stock Companies to meet their Shareholders—when there is a dividend to declare; or, at least, satisfactory progress to report. Proprietors are ever anxious to learn the actual condition of their investments, and look forward with considerable interest to the periodical renderings of their responsible men. Few of the persons who invest capital in telegraph property are aware of the extraordinary disadvantages under which their Directors labour, or of the onerous duties devolving upon their officers. Not only are difficulties experienced in raising capital at the outset, but obstacles are met with at every stage in the progress of the work, and even when the line is completed, competition frequently threatens to impair the value of the property. In submarine projects the most able Directory are often frustrated in their efforts to provide for the contingencies to which their cables are subject—the dragging of ship's anchors, damage by lightning, the discovery of faults in the most remote parts of the line—these, and a host of other disasters, have to be provided against, and yet the Directors are enabled to make these lines pay good dividends. It needs but little of the prophetic faculty to enable those who are acquainted with the nature of these investments to foretell that, so soon as several impediments to the complete success of subaqueous telegraphy are removed, that the value of this description of property will be increased tenfold.

Some idea of the internal economy of Telegraph Companies may be derived from a perusal of the reports published from time to time. The Directors of the Universal Private Telegraph Company, which was established to promote the more general use of Professor Wheatstone's beautiful instruments, held their annual meeting on the 23rd ult., and submitted their accounts, made up to the 30th August, 1862, at which date they exhibited a favourable result, except as regarded the capital account, which was clearly insufficient to develope the works commenced. The Directors found it necessary to obtain certain modifications in their agreements with Professor Wheatstone, which he cordially acceded to. These arrangements having been completed, the Directors proceeded to distribute among their friends the balance of the share capital which was subscribed for in Glasgow and Manchester; but as it was deemed advisable to encourage an interest in other towns, especially as it was understood that Newcastle and Liverpool desired to take a pecuniary interest in the Company, 827 shares were reserved for that purpose. After encountering considerable obstacles the Directors secured the consents requisite to the introduction of the Company's wires into Liverpool, and the works are progressing very satisfactorily in that town. At Manchester, Newcastle, Glasgow, and Belfast, the system has been developed in a very satisfactory manner, with every prospects of remunerative business. The entire accounts presented, made up to the 31st September last, showed a total expenditure of £61,764 0*s.* 5*d.* on the revenue account. The balance standing to the credit of the Company in August having been brought forward, the net revenue amounted to £3812 7*s.* 7*d.*, out of which a dividend of 5 per cent. was declared (which will absorb £1784 6*s.* 2*d.*), leaving a reserve of £2028 1*s.* 5*d.* Thus it will be seen that the telegraphic business of the United Kingdom is gradually extending itself, and becoming more generally appreciated than was anticipated a few years ago; and, notwithstanding the competition which now exists in all large towns, we must congratulate the Universal Private Telegraph Company upon being able to declare so satisfactory a dividend.

The half-yearly meeting of the Submarine Telegraph Company was held on the 4th instant, and the report presented was certainly very encouraging, though replete with stories of vicissitudes by land and sea. From this interesting document we learn that two of the cables had become inoperative: the Emden cable under repair, and the Danish line is being in the hands of the Austro-Germanic authorities. isnot allowed to be worked. The charges for repairs during the past six months have been unusually heavy, amounting to £5244. This large item in the accounts was attributable to the very tempestuous weather experienced, necessitating the constant employment of a steamer on the coast to make good the damage occasioned by the late gales. Since the last meeting of the Shareholders, a considerable reduction has been made by the different administrations in Germany in their internal traffic, which was expected to increase business to a very great extent; the Company has also been engaged in a very important lawsuit, still pending, for damage done to the Dover and Calais cable by the dragging of the anchor of a Swedish vessel, called the Gustaff Adolphe. When first the Company took their case into court it was decided that they had no right to lay their cables at the bottom of the sea, and that they could not recover for any damage done to them. It has now been legally settled by the judges that they had a right to lay their cables in the sea, and that they can recover for wilful damage done to them—a most important decision to all persons engaged in telegraphy, and one which will compel mariners in future to exercise greater care in casting their anchors on the route of a telegraph cable. A point, however, still remains for a jury to decide in this case, *i.e.*, whether the Dover and Calais cable was maliciously injured. The damage occasioned will cost £1000 to repair, but there is little doubt, if the Company obtain a verdict, about their receiving compensation from the defendants, as they are highly respectable gentlemen in Sweden, connected with a house of business in London. Notwithstanding these drawbacks the Directors were enabled to recommend a dividend of 4 per cent. per annum, although the capital had been largely increased by the issue of New Stock; to add the sum of £2518 8*s.* 2*d.*, being 10 per cent. on the receipts to the revenue fund; and to carry over £774 13*s.* 9½*d.* to the next account. Mr. Courtenay (the late esteemed Secretary, who recently accepted an appointment from Government in connection with the Indo-European Telegraph), has been succeeded by Mr. Clare, who now fulfils the duties of Secretary and Accountant to the Company. The directory has been very materially strengthened by the appointment of the Right Hon. James Stuart Wortley, Chairman of the Atlantic Telegraph Company, and Henry Moor, Esq., M.P., Chairman of the Mediterranean Extension Telegraph Company, and we hope that submarine telegraphy will enjoy a greater immunity from disaster, as our knowledge of the conditions to be complied with in this description of work increases. The experience already gained—at a great cost certainly—will enable future projects to be carried out with a greater probability of success; and we wait with no small

degree of anxiety the union of this country with America by a line across the bed of the Atlantic. Meanwhile we must express our satisfaction with the present aspect of the telegraphic enterprise, and indulge in anticipations of the time when the whole world will be placed on speaking terms by the wire.

OUR PROSPECTS.

VERILY the Electric Telegraph is the wonder of the world! Nothing during the last few years has created so marvellous a change as the electric revolution of science. Beneath it the features of old Christendom have become changed, and its wealth and grandeur augmented. Other revolutions have scattered luminous influences over the world, peopling it with the precious things of the present and the past; but it remained for the introduction of telegraphs to bring about one of the mightiest moral and social revolutions that ever hallowed the annals of any age. The marvellous electrical agency by which the commerce of the country is being promoted and matured, as yet only in its embryo or initial state, forms one of the wondrous characteristics of the age—an age which is emphatically utilitarian and mechanical; an age of steam and electricity, of the axe and the hammer, of the windlass and the wheel—Electro-telegraphy unquestionably forms the greatest discovery in what has been termed the century of science, and every one well knows that it owes its birth, its growth, its glorious and unparalleled march, to that industrious pursuit of honourable but gainful adventure which is the very basis of England's greatness. It is the swiftest of all messengers. Omnipresence is one of the principles of its progress. Not content with making England its lineage-home, it aims to form a girdle round the globe itself, and rears measureless dominions throughout its circuits. From the steppes of the Cossacks it already flashes along its insulated path to the shores of the Atlantic ocean, and the lands of "ruined hills and broken altars" are being converted into shrines sacred to commerce, by a magnificent power which traverses the profound depths of oceans, spans territories, enfranchises commerce, and consolidates confederacies, makes the adamantine divisible, and gives to man lordship over time and space. We hail with unfeigned satisfaction the prospects of the speedy realization of an Atlantic telegraph, of which our columns of this week bear ample evidence. The fortunes of telegraphy should be no longer involved in the doubtfulness of experiment—the system is no longer a theory. And we trust that now, on the eve of the ultimate attainment of great and magnificent results, that those who so long have stood steadfast to the "good cause," will not be turned aside from the path of victory when in sight of the goal and the fruit of their labours and anxieties handed over to others who never took any part in earning it.

It has frequently been our duty to illustrate, by the state of trade and commerce existing at the moment, and by reference to the simultaneous condition of telegraphic revenue and profits, the sympathy, almost amounting to mutual dependence, which may be discovered in the relations of all the great departments of business by which the position of England at the head of the world in arts, arms, civilisation, and humanity, must continue to be maintained until the far-distant period of our declension in the scale of nations. It is not so much the tacit and indolent recognition of great economical and social truths, as the impression they make on the acting minds of men, that gives importance to the continued and emphatic enunciation of them. Much as the attention of ingenious and clever men has been directed to the scientific questions connected with the progress of electricity, the *statistics* of telegraphy—those branches of their operation which exhibit their harmony with the springs of the nation's strength and happiness—remain in the obscurity of comparative neglect. They have not been brought so closely *en rapport* with men's immediate contemplations of self-interest as older subjects, of infinitely smaller importance, but which have the advantage of familiarity, and of that "association of ideas" that exercises so great an influence over the fancy rather than over sober judgment. It may even yet take a long time before the world is prepared to understand how large a part a mere novelty is playing, and how much a larger one it yet has to play in the influences and transactions on which the vitality of the empire depends, and on which depends the subsistence of the thousands of new subjects who are yearly born to the leal service of our excellent Queen. But these practical truths cannot very long hide themselves; they must become known by their effects, even if we foolishly shut our eyes to them until they are forced on our notice by the dearest of all lessons—those taught by experience. As in cases of this kind a world of subsequent tribulation and loss may be avoided by a community recognising in time the indications of great though new events, and preparing itself to take advantage of them, rather than engaging in an effort to stop the eternal progress of mind and nature, we think we shall be doing good service to society by continuing to remove misimpressions, and to raise up correct and adequate ideas upon a subject in which we feel all the public to be profoundly interested.

INDICATING AND DISPERSING FIRE-DAMP IN MINES, &c.

THE immense loss of life which has from time to time taken place from the generation and accumulation of fire-damp, &c., in coal-mines, has naturally led many scientific men and others to endeavour to devise means of averting the recurrence of such catastrophes. The Geordie and Davy lamps have rendered valuable services to the miners, have been the means of saving the lives of hundreds, and have rendered a large amount of property productive that the proprietors were unable to turn to any profitable account; still the danger arising from working in coal-mines, where inflammable and explosive gases are generated, is a source of constant apprehension on the part of the miners and the proprietors. Our attention has recently been called to a very simple and ingenious contrivance for indicating the presence of fire-damp or choke-damp in mines, for dispersing the same, and also for telegraphing in mines, by Mr. E. N. Gisborne. The fire-damp, or hydrogen gas, which is generated in a coal-mine, is of less weight or specific gravity than the atmospheric air; and the choke-damp, or carbonic acid gas, in a mine is of greater weight or specific gravity than the atmospheric air; and the invention of Mr. Gisborne consists in the employment, in combination with suitable apparatus, of these relatively lesser or greater weights to connect an electric circuit, and thereby cause the required indication or signals to be given. The following are some of the modes in which weight or pressure are employed for the purpose:—In a glass vessel or chamber, which is open at one end, is suspended a delicately poised lever, and the mouth of the vessel is closed and rendered air-tight by means of a double layer of very thin india-rubber, strained over a ring, so as to leave a clear space of about half an inch between the layers; a small stud of metal is then inserted in the inner layer, immediately over the upper end of the lever, and a wire from the battery is also passed through the side of the vessel into the space between the two layers, so that its point may nearly touch the metal stud, and a wire is also passed through the side of the vessel below the inner surface of the inner layer, and its point brought nearly to the end of the lever, so that when the atmospheric air in the vessel is expanded by the agency of lighter gases, the inner layer is pressed upward, and the metal stud is brought into contact with the wire between the layers, and the circuit is thereby completed; and on the other hand, when the upper surface of the layers are deflected by the agency of heavier gases thereon, the upper end of the lever is depressed, and the lower end being thereby brought into contact with the wire in the vessel, the circuit is completed. The like results are obtained by the means of the pressure of the gases on

a vacuum chamber similar to that in an aneroid barometer. The like pressure contact is also employed to connect an electric circuit through a Ruhmkorff coil and condenser, and by causing the current to pass thence between two metal points placed *in vacuo* in the interior of a glass bulb or chamber, to illuminate such bulb or chamber; and the like pressure contact is employed to connect an electric current from a battery at the surface, and by a galvanometer or electro-magnet withdraw an opaque slide from the front or back of a coloured bull's-eye in a Davy lamp, and expose the coloured light. The drawal and withdrawal of the slide in a Davy lamp by the means mentioned is employed, and also the illumination of the bulb or chamber, for the purpose of telegraphing or communicating signals from one part of a mine to another, or from the interior thereof to the surface or pit's mouth by arbitrary signs; thus, for example, a continuous red light may be used to signify "danger from fire-damp;" two movements may mean, "send down the cage," and so on; and in like manner, one, two, or more flashes or illuminations *in vacuo* may be used to signify pre-arranged sentences. The pressure contact is also employed to give signals by releasing or moving an electro-magnet, to sound an alarum, ignite an explosure compound at the surface, or otherwise indicate danger. The fire-damp may be dispersed by forcing it as it is generated by means of the pressure contact, completing the circuit, and igniting some explosive compound.

THE AUTOMATIC TELEGRAPH OF MR. THOMAS ALLAN, C.E.

BOTH in this country and in France great changes in our existing telegraphic systems are under discussion, and it is certainly high time that some great reform—or, to say the least, some great advance—were made in the matter. The time has now arrived when it must be made known that telegrams in this country cost much more than they ought, not chiefly on account of the large profits made by the existing companies, but rather because the improvements which have been made in telegraphic apparatuses have put into our hands the means of doing what those companies with costly contrivances, cannot afford to do. Unfortunately for them (and for the country also) it is impossible to engraft many of the most important modern improvements upon the apparatus now in use. What we require is to commence a new and improved telegraphic system *ab initio*, so that we may give the public the benefit of all the great advances which have been made in the construction of telegraph instruments.

Ever since the telegraph has been open to the public, the number of messages sent by it have been, as might have been predicted, continually on the increase. If we can succeed in lowering considerably the present high price of the telegram, who can doubt that the number would be correspondingly multiplied? The postal system, which is of a character essentially similar to that of the telegraphic system, shows us what we may fairly anticipate. Since the cost of postage was made low, and uniform throughout the kingdom, the number of letters sent by post annually has been increased nearly seven-fold, being 82,470,596 in 1839, and 600,000,000 last year! Now, what we desire is to imitate this progress (proportionately) in our telegraphic system; and to do this it is only necessary, we are persuaded, first to make the cost of a message low, say a *shilling* for fifteen words, and next, to make this cost uniform for messages sent to any part of the kingdom.

Now, the question arises—can a telegraphic system be so established throughout the United Kingdom as to render a uniform shilling message remunerative? We answer, without doubt. But such a system must embrace many novelties. It must for example, be so arranged that the mechanical manipulation of the instruments shall approximate much more nearly than at present to the speed of the electrical operations. As telegraph lines are now worked, the capabilities of the wires to transmit electrical impulses are not nearly developed, owing to the comparative sluggishness of our mechanical operations. This defect must be removed; we will show presently how it may be.

The person to whom we are indebted for several most important improvements in electric telegraphs—improvements embracing all that we have just been considering—is Mr. Thomas Allan, C.E., the author of many valuable telegraphic inventions. Mr. Allan has introduced telegraphic improvements which it is impossible to estimate too highly. The first of these which we will mention relates to what are called pole-chargers, or relays. A great difficulty with these has hitherto been the derangement caused by the action of the spark upon the delicate contact points of the relay. Now, this evil Mr. Allan has got rid of altogether, by combining an improved relay with an improved recording instrument, in such manner that the spark is not produced in the relay at all, but in the recording instrument, where it is of far less consequence. This improvement is attended by an immense advantage, for, now that the relay is relieved of the spark, the limit which has hitherto been practically placed upon the power of the local battery is removed. In Mr. Allan's recording instrument, every current makes a sign, as the relay does not require an opposite current to put it in position to print the next mark, as is generally done, nor does it need any spring or weight to bring it to a position in which the local circuit may be cut off; the printing magnet does that. This magnet also draws through the paper on which the message is to be received while (and only while) the signalling is continued. The new sending instrument by Mr Allan is of a similarly automatic character, all that is necessary being the mere putting of the message (that is, a perforated strip of paper) in the machine.

By the improvements thus far described, the whole progress of sending and receiving messages is made immediately and solely dependent upon the electrical impulses. The electricity performs all itself, neither the hand nor the brain of man being required to interfere. This is a great improvement. The old system, in which the speed at which the hand and the brain of the operator can work rigidly limits the speed at which messages are sent. Mr. Allen might, therefore, have stopped at this point with satisfaction; but he has fortunately chosen to go beyond it, and invented a machine for preparing the message—that is, the perforated paper before spoken of—in a ready and rapid manner. It is clear that by multiplying the number of operators employed, these perforated messages may be produced as rapidly as the electrical instruments can transmit them.

The economy which must attend the introduction of the foregoing improvements is very great. The rate of telegraphing will be increased from two to three-fold, whilst the operation will be reduced to a mechanical one merely, and so secure the economy of machine work as compared with manual or skilled labour; moreover, the apparatus being thus rendered automatic, the primary cause of the mistakes and blunders which are now so much complained of will be removed. The message will be independent of the fallibility or inattention of the operator; whilst, also, a record of each message sent and received is retained at either end, thus forming a complete check upon both the operator and the machine.

EXPERIMENTS ON AERIAL INSULATION.

Two miles of copper wire were insulated upon about 200 porcelain inverts and terminals on lofty standards, and the ends of both miles of wire led into the experiment-room. The two miles could be used together or separately, as occasions might require. In the experiments on insulation for dynamic electricity, the instrument employed was a very delicate galvanometer, having 30,500 coils of copper wire $\frac{1}{1000}$th of an inch in diameter, covered with silk, and the needle suspended by an unspun silk thread. The instrument made use of to measure the retention of the charge of static electricity was a Peltier electrometer kept in a glass-covered zinc box, supplied with chloride of calcium to avoid humidity. A Daniell's battery (Muirhead's improved) of 512 elements was employed for charging both with static and dynamic electricity. The battery was thoroughly insulated by being suspended by straps of gutta-percha made fast to the rafters of the flooring above, and the electromotive force of the batteries often ascertained during the experiments by means of the Peltier electrometer. The battery being always carefully attended to and insulated, as above described, maintained a very regular amount of tension. On the 10th of August, 1860, the whole of the insulators were cleanly washed, and then dried with towels. As soon as the insulators were thoroughly dried, both wires were tested for insulation for static electricity, but neither would sustain the charge an instant. When tested for the loss of insulation for dynamic electricity, the loss of insulation was 1° and 2°, but a slight shower of rain increased the leakage to 18°, which was again reduced to the original figure as the insulator became dry.

The waves of air, as they passed over the insulators, absorbed each a portion of the moisture, and the passage of these waves, or currents of air, was beautifully displayed by a corresponding wave-like movement of the indicator, showing the progress of drying, and consequently of improved insulation. A drizzling mist acted upon the insulators by decreasing the insulation in a similar wave-like manner. The insulators were again thoroughly wiped with dry towels, and the following tests made:—Temperature of experiment-room, 69°; in the sun, 70°. Loss of insulation for static electricity on both wires, 50° in four minutes. Loss of insulation on dynamic electricity, none. One insulator being thoroughly wetted within and without, the loss of insulation was 6°; on two, 8°; on three, 9°; on four, 11°. These four insulators having again been dried, the current was kept on the wires. No loss was observed, but upon causing a column of smoke to ascend, so as to come in contact with the wires and a few of the insulators, the needles were instantly deflected, and indicated a leakage or absorption of 4°, with a continuous vibrating motion through an arc of 1·5°. The smoke having ceased to ascend, no loss of insulation was further observable on the dial of the instrument. Shortly after three P.M., dark and heavy clouds passed over the neighbourhood; the effect upon the needle was peculiar. It was not what might be called exactly "vibration," but an undulatory motion, now slightly to the right, then to the left, &c. Some of the dark clouds appeared as if they attracted the needle upon their approach, and in receding repelled it; or, in other words, to reduce the tension of the electricity in the wires as they approached by absorption or otherwise, and, as they receded, momentarily to enhance to a small degree that tension. During thunderstorms and lightning the motion of the needle, when under a full battery charge, and in connection with the insulated wire, was generally tremulous—a tendency to "dip" rather than to deflect angularly; but on one occasion, during a heavy thunderstorm in the autumn of 1860, the needle suddenly fell to zero, but instantly regained its original position of 32°. During the course of the day several instances occurred, when the needle suddenly deflected 3° or 5°, without any apparent cause. Ultimately it was traced to the passage across the wires of the steam from the railway locomotives, which passed within a few yards of the suspended wires. Numerous experiments were subsequently made upon the effects of the currents of steam. It was generally found that when dense columns of steam came in contact with the wires or the insulators, a disturbance of the needle took place. The condensation of steam is very slow in some kind of weather, and it has then a greater effect when it has been carried by the wind against the wires along our telegraph lines. It would be an interesting procedure to determine upon some of our long lines the effect of steam upon their insulation, and how far it may be the cause of the capricious deflections of our signalizing needles, which are generally attributed to earth currents, cross contacts, &c. The locomotive at times, during its progress, is in close proximity to the wires; at other times the wires are at a distance, and not liable to be affected, especially when traversing a tunnel in which the wires are wholly insulated, the foot of an embankment, or high elevations. The effect of these irregularities in the relative positions of the locomotive and telegraphic wires might be determined by the corresponding changes in the insulatory condition of the line upon some fine and dry days, as indicated upon a galvanometer. When the suspended wires were charged with static electricity, its absorption by steam was instantaneous. When the steam ascended, and circulated amongst the insulators, it not only wetted the surfaces, but condensed in the inverted hollows, or bells of the insulators, and for a time afforded a ready passage for the fluid to the earth in the same manner as the morning dew moistened the exterior, and the earth's vapoury exhalations the interior, of the inverts or terminal. What is generally designated a "dry fog" had but little effect upon insulation, but a fog charged with moisture affected it much in the same manner as the dew and rising vapours of the morning. Snow deposited upon the surface of the insulator had not the same effect as ice; the ice affects the insulation, inasmuch as it lined the external and internal surfaces of the insulator with a conducting medium; but when the insulators were clean, and free from ice, the insulation was found invariably good in frosty weather. It should, however, be observed here, that in all the above experiments, one end of the wire was always insulated—that is, not in contact with the earth—and that the other end, in testing with *dynamic* electricity, was in contact with the copper pole of the battery.

GILMORE AND PREECE'S SHIP-STEERING TELEGRAPH.

The following remarks on the new ship-steering electric telegraph appeared in a leading article of the *Daily Telegraph* on the 10th instant. This instrument is the invention of Lieutenant A. Gilmore, of Woolston, and Mr. W. H. Preece, C.E., of Southampton:—

We have chained steam to our passenger trains and our goods waggons; we make it spin and weave for us; forge, and trim, and punch the obdurate iron-plates for us; fetch and carry, raise and lower, enormous masses—a passive "slave of the lamp." We have won the lightning down from heaven to run upon our messages, to bring intelligence over wildernesses and under oceans to us from the ends of the earth. Our last achievement now is to impress this domesticated electric spark into the Queen's navy, with the rating of "call-boy." Go on board the Resistance, Hector, Prince Consort, Orlando, or her Majesty's own yacht, and you will see in front of the wheel what resembles a dial-stand, with a plate and movable indicator; on which at night shines a lamp, to make visible the words "steady," "starboard," and "port." Utterly bewildering to the old Benbows and Hoods—strange to the rough sea-dogs who won for us our place upon the waters—would seem this appendage to the fittings of a man-of-war. But they would own the use of it in a raging gale, or when the bustle and noise of action began. A wire passes from the plate to the post of the officer in command, who has but to touch a key-handle, and the needle under the steersman's eye moves to "port" or "starboard," conveying him the order. Lest, for want of the old loud command, he should be thinking of his next allowance of grog or his last sweetheart, and so overlook the message, a gong strikes below the dial at the same moment, and by the number of its sounds he can tell how many points he is to port or starboard his helm; while, should the commander want it put "*hard* up" or "*hard* down"—that is to say, sharply and roundly done—the strokes are given with corresponding rapidity. To appreciate this a landsman ought to have been on board a vessel heeling over in a China typhoon or Mediterranean "mistral," when the captain's or the quartermaster's bellow through the speaking-trumpet is blown into vague breath at its very mouth. He ought to have gone into action with a heavy ship, when all her great guns are roaring at once, and it matters as much as life or death, defeat or victory, to get a turn upon the wheel at the very nick of time. Or he should have made one of a crew by night, when the darkness is so dense that "you can feel it," and when suddenly there glower out of the blackness the lamps of a large vessel bearing down upon the ship, "end on." Without this electric call-boy the all-important word of command must pass—in a gale of wind too, perhaps—from end to end of the deck. It may be misunderstood, mispronounced—the steersman touches the wheel too late, or perhaps wrongly—and the two great hulls come together in the gloom with a crash that brings masts and gear in a tangle atop of the sinking sailors; there are wild shouts, vain efforts, the gurgle of two vast whelming masses, some screams that pierce the night, and—"Lloyd's List" reports months after that the Red Rover and the Mary Jane are "*still missing*." What her Majesty's new naval volunteer Lightning will do in the battles of the iron-clads remains to be seen; but it is hardly possible to comprehend how the cupola-ships, with their ponderous guns and swift antagonists, depending as they must upon twin screws and instantaneous manœuvres, could wage the new warfare successfully without some such aid.

But we like better to contemplate the peaceful uses of these great gifts of science; for towards peace and the happy future identification of the interests and energies of all nations these gifts undoubtedly tend. Do we reflect enough upon what science has done for us, and is doing every day, to render life nobler, higher, more benign, and less mechanical? Is the truth sufficiently grasped, that the daily existence of the artisan or middle-class worker among us is, in a thousand things, incomparably more luxurious through science than that of the nobleman or monarch in what we call, with more conventionality than truth, the "good old times?" Science, and her sister Commerce—the twin earthly angels of human fate—are always working to substitute the machine for the slave, the forces of nature for the aching muscle, the strong action of steam and the swift flash of electricity for the ancient and tedious agents of labour and locomotion. In hundreds of instances, the reader of these very lines can be the witness. He has, if he is tolerably well off in the world, risen to a breakfast table towards which, though

but modestly furnished, the four quarters of the world have contributed their tea, sugar, silver, cloth, condiments, and utensils. Instead of rushes under foot, his slippers have rested on a carpet that, in King John's time, would have bought a baron's estate for its marvellous manufacture. On his table lies this journal; printed at a speed inconceivable until the dazed eye has actually witnessed its fluttering thousands flying off the cylinders. James Watt made it possible for him to read the news of all the world as regularly as he munches his muffins; and Wheatstone enabled us to bring it for him from India, America, Denmark, the Danube; so that Ariel's girdle is put round the world in his daily experience. Hydraulic engineering has given him, at a finger's touch, his bath and the water for his toilette, instead of sending his household far out of doors, as in Asia, to the tank or the well. He throws himself into a comfortable carriage, and steam's tireless arm drags him, at a speed which makes the coaching days ridiculous, to his business or office. There, if he has a parcel to deliver hurriedly, the Pneumatic Despatch Company will shortly puff it for him like a pea from one end of London to the other; and if affairs necessitate a message to the further side of Europe, or domestic arrangements make it needful to say something about dinner or the babies, a small blue spark flashes through space for him, and his wish is known as soon as conceived. The paper he writes upon, the gas-lights by which he writes, the book he takes home, the engraving after Landseer or Millais that catches his eye on the way and leaves a thought of beauty in his mind—the *now* commonest objects of his every-day life, with which not only would he not dispense, but without which existence seems inconceivable—are the gifts of science to this his present day. They have insensibly embellished and elevated his daily duties and labours; they have made Nature the helpmeet, instead of the mystery and Mumbo-Jumbo of his world; they have raised labour many stages above the senseless service of machinery. He cannot walk, or sit, or travel, or work, or communicate with his fellows, but there are helps for him to everything, that demonstrate what the silent closet of the philosopher is doing, and has done, for the ever-widening destinies of man.

Signs are not wanting, too, that a vast development of these benignant aids to human life is approaching. A cautious induction from optical experiments has lately ended in disclosing to us something of the structure of the sun and planets, and even the fixed stars, although so far off that a fractional difference in the rate of light's velocity sets these bodies nearer or more distant by tens of millions of miles. Photography, which has made the same sun our portrait-painter upon cheaper terms than any peripatetic silhouette-cutter, and with finer detail and truth than the best ivory miniatures, seems to be trembling on the verge of producing colour, as well as light and shade. Comparative anatomy, enriched by the products of incessant travel, at least approaches to the solution of the absorbing problem of man's origin. Geography is gradually mapping out the earth for us, though the honours which are showered on courtiers are denied to the discoverers of the fountains of the Nile. Yet, recognised or unrecognised, Science pursues her patient toil, and "knowledge increases." Were this merely a material gain, it would be less important. Science, however, is not the enemy, but the true and faithful handmaid of real religion, and raises us higher only to show how boundless and beautiful is God's universe—how fair the capabities of creation—how noble the prospects of humanity, how grave its duties—how adjusted and fitted to the one great work of moral development is every object and combination among the things which surround us. And though the highest wisdom will still most often teach us our utter ignorance—though the best adornments and greatest alleviations of life will still throw into sharper and more painful contrast its inequalities, injustices, and miseries—yet to have so much is to be promised so much more. Eternally the circles of Divine influx widen upon the sea of human life, and new angels "trouble the water" with stronger and more health-giving impulses. Knowledge breeds knowledge—invention, invention; and their use and exercise a growing tendency to peace. Bigotry opposes it; men's vices and prejudices delay it; ambitious dynasties stand in its way; and the voices that proclaim it are few, and often silenced by selfish policies and ignorant wit; but the days approach—though distant, perhaps, by centuries—when even here there will be "no more war," and man's life be made consistent with his glorious capabilities.

REDUCTION OF TARIFFS.—The highest charge for a message of twenty words to any town in the United Kingdom is three shillings. The reduced charges came into operation on the 7th instant.

ELECTRICAL DISCOVERIES.

I.

A SHORT account of the various discoveries in the science of electricity which took place in the seventeenth and eighteenth centuries, we presume, will not be uninteresting to our student readers. It will be seen how the progress of science prepared the way for the more glorious and magnificent discoveries of the nineteenth century, resulting in the realization of the electric telegraph and its wonderful capabilities, as evidenced in our time, in the transmission of intelligence, both by sea and land, between the nations of the civilised world.

In the year 1600 William Gilbert, a native of Colchester and a London physician, published a Latin treatise, "De Magneto," having discovered that sulphur, wax, resinous substances, glass, and precious stones, when dried and rubbed a little, were endowed with the property of attracting and repelling straws and other light substances.

In 1630 Nicolaus Cabœus, at Terrara, repeated Gilbert's experiments, and made some progress, increasing the list of electrics; as also did Mr. Boyle in the year 1670. He made some discoveries which had escaped the observation of those who preceded him. Contemporary with Mr. Boyle, Otto Guericke, burgomaster of Magdeburg (inventor of the air-pump), made some advances. He constructed a sulphur globe, which he mounted upon an axis in a wooden frame, and causing it to revolve, at the same time rubbing the globe with his hand, performed a variety of electrical experiments. He was the first to discover that, a body once attracted by an excited electric, was repelled by it, and not again attracted until it had touched some other body. He observed the light and sound produced by the electric fluid while turning his electrical machine. Dr. Wall, about the same time, observed the light and sound produced by rubbing pieces of amber with wool, and also experienced a slight shock. He compared the sound and light of the electric fluid so produced to thunder and lightning.

Sir Isaac Newton also engaged in similar experiments in electricity, and was the first in 1673 to discover that excited glass attracted light bodies on the side opposite to that on which it was rubbed, and gave an account of his experiments to the Royal Society in 1675.

Mr. Hauksbee, whose writings are dated 1709, distinguished himself by experiments and discoveries in electrical attraction and repulsion, and electric light. He constructed an electrical machine, adopting the glass instead of the sulphur globe. He experimented upon the subtilty and copiousness of the electric light, and likewise upon the sound and shocks produced by the fluid. After the death of Mr. Hauksbee the science of electricity made but slow progress, and few experiments were made for twenty years. In the year 1728, Mr. Stephen Grey, a pensioner at the Charter House, commenced his experiments with an excited glass tube. He and his friend, Mr. Wheeler, made a great variety of experiments, in which they demonstrated that electricity may be communicated from one body to another, even without being in contact, and in this way may be conducted to a great distance. Mr. Grey afterwards found that, by suspending rods of iron (which was the origin of metallic conductors) by silk or hair lines, and bringing an excited tube under them, sparks might be drawn, and a light perceived at the extremities in the dark. He electrified a boy suspended by hair-lines, and communicated electricity to a soap-bubble blown from a tobacco-pipe. He electrified water contained in a dish placed upon a cake of rosin, and also a tube of water. He made some curious experiments upon a small cup of water, over which, at the distance of an inch, he held the excited tube. He observed the water to rise in a conical shape, from which proceeded a light; small particles of water were thrown off from the cone, and the tube moistened; and from other experiments he concluded that the electrical power seemed to be of the same nature with that of thunder and lightning. The following is a description of some of the experiments by which the ingenious pensioner arrived at his electrical discoveries:—After attempting in vain to give the power of attraction to metals by rubbing, hammering, and heating, he conceived a suspicion that, as glass when rubbed in the dark communicated its light to other bodies, it might possibly be made also to communicate its power of attraction. He provided himself, therefore, with a glass tube, 3 feet 5 inches long and near 1¼ inch in diameter. The ends of the tube were stopped with cork; and he found that when the tube was excited by friction, a feather was

attracted as powerfully by the cork as by the tube itself. To convince himself more fully, he procured a small ivory ball, which he fixed to a stick of deal 4 inches long, and thrust into the cork; and he found that it attracted and repelled the feather, even with more vigour than the cork itself. He afterwards fixed the ball to a longer stick, and even to a piece of wire with the same success. Lastly, he attached it to a piece of pack-thread, and hung it from a high balcony, when he found that, by rubbing the tube, he enabled the ball to attract light bodies in the court below. His next attempt was to examine whether this power acted as well horizontally as perpendicularly. With this view he made a loop of cord, which he hung to a nail in one of the beams of the ceiling, and ran his pack-thread, which had the ivory ball at the end, through the loop; but in this he found, to his utter mortification, that his ball had lost totally the power of attraction. On mentioning his disappointment to a friend, it was suggested that the cord which he employed for the loop, through which the pack-thread run, might be so coarse as to intercept the electric power. To remedy this they made the loop of silk, which they considered stronger in proportion to its thickness than the former. With this apparatus they succeeded beyond expectation. As they attributed their success entirely to the fineness of the silk of which the loop was made, they thought they would perform still better by supporting the pack-thread by a very fine brass or iron wire; but, to their utter astonishment, the electric power was entirely lost; on the contrary, while the apparatus was suspended by the silk loops, they were able to convey the power of attraction along a pack-thread of 765 feet in length. It was evident, therefore, that these effects depended upon some quality in the silk which disabled it from conducting away the electric power on the hempen cord as the wire had done; and by subsequent experiments this hypothesis was amply confirmed.

Mr. Du Fay, intendant of the French king's gardens, repeated the experiments of Mr. Grey in 1733. He found that by wetting the pack-thread he succeeded better with the experiment of communicating the electric virtue through a line 1,256 feet in length. He made the discovery of two kinds of electricity, which he called *vitreous* and *resinous*; the former produced by rubbing glass, and the latter from excited sulphur, sealing-wax, &c. But this he afterwards gave up as erroneous. Mr. Grey, in 1734, experimented upon iron rods, and gave rise to the term *metallic conductors*. He gave the name, *pencil of electric light*, to the stream of electricity, such as is seen to issue from an electric point. He suggested the idea that the electric virtue of the excited tube was similar to that of thunder and lightning, and that it could be accumulated.

OPINIONS AS TO THE PRACTICABILITY OF DEEP-SEA TELEGRAPHS.

[*Extracted from the Evidence taken before the Government Telegraph Committee.*]

WE desire, however, in conclusion, to observe that we are clearly of opinion that the failures of the existing submarine lines which have been described, have been due to causes which might have been guarded against, had adequate preliminary investigations been made into the question, and we are convinced that, if regard be had to the principles we have enunciated, in devising, manufacturing, laying, and maintaining submarine cables, this class of enterprise may prove as successful as it has, hitherto, been disastrous.—*Member of the Telegraph Committee appointed by the Board of Trade.*

I have no doubt that you can lay a cable in almost any depth of water, if you apportion its specific gravity, and its strength, according to the depth at which it is being laid. * * * So that I think the question of laying cables in deep water, as a question of laying, is not more difficult to solve than the question of laying a cable in shallow water, if the proper mode of construction is adopted.—*The late L. Gisborne, Esq., C.E.*

I think a cable could be laid at 3,000 fathoms. * * * I do not think that a depth of 3,000 fathoms is an insurmountable difficulty.—*Richard A. Glass, Esq.*

I can see no real obstacle to the successful laying and permanent working of an Atlantic cable.—*Captain J. Kell.*

I think that submarine cables can be laid in any reasonable depth of water, say 2,000 or 3,000 fathoms.—*Mr. Willoughby Smith.*

Once in deep water, and the deeper the water the better, the more safe the cable is, in my opinion; and I may say, also, that I feel the utmost confidence in being able to lay a light cable with the greatest possible ease. Almost every nautical man that I have talked to on the subject has said, "If we had only just a very light cable, that could be paid out, like paying-out a log line, there would be no difficulty at all about it."—*J. A. Longridge, Esq., C.E.*

I have very little doubt, from the experience gained by the repeated attempts to lay the Atlantic cable, that if a cable be properly made, and once laid, it must result in permanent success. * * * I am not aware of any inherent difficulties that are not easily surmounted.—*W. H. Woodhouse, Esq., C.E.*

I have no doubt as to the permanency of deep-sea cables, if they are perfectly constructed, and perfectly laid upon a soft bottom, and provided they are worked with proper currents.—*Sir Charles Bright, C.E.*

My opinion is that a cable can be so thoroughly well-made as to last 50 years, if laid down in quiet water, without further expense. —*The late J. W. Brett, Esq.*

I think an iron-wire covered cable can be laid at a depth of a mile and a-half, or between 1,400 and 1,500 fathoms.—*Mr. W. T. Henley.*

I must say it is my entire belief that if you can once properly safely submerge a properly constructed cable in the deep ocean, it will, in all probability, last for hundreds of years.—*George Saward, Esq.*

It did not appear to me that there was any difficulty in paying-out the Atlantic cable, which is now laid; but I think it would be an improvement if a cable of equal strength, and of smaller weight, could be adopted.—*Commander J. Denman, R.N.*

I would not have the slightest hesitation in laying a cable of that size (the Gibraltar cable), made of steel and hemp, in 2,000 fathoms.—*H. C. Forde, Esq., C.E.*

I think as the result of the whole of my experience, that with proper skill, and suitable machinery, either heavy or light cables may be laid in deep water.—*R. S. Newall, Esq.*

THE INTERNATIONAL EXHIBITION, 1862.

(*Continued from page 127.*)

7. *Automatic Systems for the Transmission of Messages in the Codes described.*

Four distinct plans for transmitting by *automatic mechanism* messages, expressed in the codes already mentioned, are exhibited respectively by—

The Universal Private Telegraph Company [Professor Wheatstone, Juror] (United Kingdom, 2,978).

Digney Brothers & Co., Paris, M. (France, 1,414).

Siemens & Halske, Berlin, M. (Prussia, 1,413).

T. Allan, M. (United Kingdom, 2,850).

It has long been known that messages might, through most land lines, be received legibly, when the separate signals succeeded each other much faster than a clerk could send them, when each symbol required a separate movement and act of volition on his part. Many plans have consequently been devised for the indirect or mechanical transmission of signals, as opposed to their direct transmission by hand. In all these plans, the message is in some way mechanically represented—for instance, by punched paper or by arranged types; the preparation of the paper, types, or their equivalent is to be carried on simultaneously by several clerks, while the prepared messages are being successively transmitted with great rapidity through a single wire; so that if, say, by the present system the capabilities of a line were 300 messages per diem, it is supposed that by the automatic system, 1,500 or 2,000 messages might be sent through the same wire in the same time, at very slightly increased cost. The possible fallacy of these expectations has already been alluded to, but some of the plans now exhibited are so admirable in conception, and so simple in execution, as to warrant at least a hope that the difficulties alluded to may be successfully overcome. If, indeed, the public could be induced to learn a telegraphic alphabet, and to *prepare their own messages*, the success of the automatic system might be expected with much confidence. Thus, a merchant's clerk might prepare the messages of the firm in the punched paper required for Professor Wheatstone's transmitter; this prepared paper, on delivery at the telegraph office,

would simply have to be passed through the machine when its turn arrived, and the corresponding dotted tape received at the distant station could at once be addressed and delivered to be deciphered by the receiver at his leisure.

The functions of a telegraph company would then be nearly similar to those of the present post-office. The messages of prepared paper received would have to be sorted and transmitted in batches to the several towns by being passed through a machine at one end of a wire, at the other end of which the counterpart would appear. These counterparts would then have to be again sorted, addressed, and sent out as letters are now. Every yard of paper passed through the machine might be charged at a certain rate without any reference to the code, language, or number of words. No great skill would be required to prepare or decipher the message, since these operations could be done leisurely; the functions of the company would be reduced to those strictly essential, and their responsibilities much diminished. Although seeming somewhat visionary at present, it is just possible that some such plan may some day be adopted, and that telegraphic despatches may then be sent as cheaply as letters are now; but so long as companies are required to prepare the messages at one end of a wire, and to write them out fairly at the other end, the writer doubts whether automatic systems will come into general use.

The advantages of the automatic system are very distinctly set forward in a paper by Professor Wheatstone, published in the "Comptes Rendus of the Paris Académie des Sciences." From this paper is mainly extracted the following description of the admirable instrument invented by Professor Wheatstone, and exhibited by the Universal Private Telegraph Company (United Kingdom, 2,978):—

"Long strips of paper are perforated by a machine constructed for the purpose, with apertures grouped to represent the letters of the alphabet and other signs; a strip thus prepared is placed in an instrument associated with a rheomotor (or source of electric power), which, on being set in motion, moves it along, and causes it to act on two pins in such manner, that when one of them is elevated the current is transmitted to the telegraphic circuit in one direction, and when the other is elevated it is transmitted in the reverse direction; the elevations and depressions of these pins are governed by the apertures and intervening intervals. These currents, following each other differently in these two opposite directions, act upon a writing instrument at a distant station in such a manner as to produce corresponding marks on a slip of paper moved by appropriate mechanism.

"The first apparatus is a perforator, an instrument for piercing the slips of paper with the apertures in the order required to form the message. The slip of paper passes through a guiding groove, at the bottom of which an opening is made sufficiently large to admit of the to-and-fro motion of the upper end of a frame containing three punches, the extremities of which are in the same transverse line. Each of these punches, the middle one of which is smaller than the two external ones, may be separately elevated by the pressure of a finger-key. By the pressure of either finger-key simultaneously with the elevation of its corresponding punch, in order to perforate the paper, two different movements are successively produced: first, the raising of a slip which holds the paper firmly in its position; and secondly, the advancing motion of the frame containing the three punches, by which the punch which is raised carries the slip of paper forward the proper distance; during the reaction of the key, consequent on the removal of the pressure, the clip first fastens the paper, and then the frame falls back to its normal position. The two external keys and punches are employed to make the holes, which grouped together represent letters and other characters, and the middle punch to make holes which mark the intervals between the letters.

"There need be no change in the alphabet which is at present employed; the points at one side may represent the short dashes, and those at the other side the long dashes, their order remaining the same as in the existing system.

"The second apparatus is the transmitter, the object of which is to receive the slips of paper prepared by the previously described instrument or perforator, and to transmit the currents produced by a voltaic battery or other rheomotor, in the order and direction corresponding to the holes perforated in the slip. This it effects by mechanism somewhat similar to that by which the perforator performs its functions.

"An eccentric produces and regulates the occurrence of three distinct movements. 1st. The to-and-fro motion of a small frame which contains a groove fitted to receive the slip of paper, and to carry it forward by its advancing motion. 2nd. The elevation and depression of a spring-clip, which holds the slip of paper firmly during the receding motion, but allows it to move freely during the advancing motion. 3rd. The simultaneous elevation of three wires placed parallel to each other, resting at one of their ends over the axis of the eccentric, and their free ends entering corresponding holes in the grooved frame. These three wires are not fixed to the axis of the eccentric, but each end of them rests against it by the upward pressure of a spring, so that when a light pressure is exerted on the free ends of either of them, it is capable of being separately depressed. When the slip of paper is not inserted, and the eccentric is in action, a pin attached to each of the external wires touches, during the advancing and receding motions of the frame, a different spring, and an arrangement is adopted by means of insulation and contacts properly applied, by which, while one of the wires is elevated and the other remains depressed, the current passes from the voltaic battery to the telegraphic circuit in one direction, and passes in the other direction when the wire before elevated is depressed, and *vice versâ*; but while both wires are simultaneously elevated or depressed, the passing of the current is interrupted. When the prepared slip of paper is inserted in the groove and moved forward, whenever the end of one of the wires enters an aperture in its corresponding row, the current passes in one direction, and when the end of the other wire enters an aperture of the other row, it passes in the other direction. By this means the currents are made to succeed each other automatically, in their proper order and direction, to give the requisite variety of signals. The middle wire only acts as a guide during the operation of the current.

"The wheel which drives the eccentric may be moved by the hand, or by the application of any motive power.* Where the movement of the transmitter is effected by machinery, any number may be attended to by one or two assistants. This transmitter requires only a single telegraphic wire.

"The third apparatus is the recording or printing apparatus, which prints or impresses legible marks on a strip of paper corresponding in their arrangement with the apertures in the perforated paper. The pens or styles are elevated and depressed by their connection with the moving parts of the electro-magnets. The pens are entirely independent of each other in their action, and are so arranged that when the current passes through the coils of the electro-magnet in one direction one of the pens is depressed, and when it passes in the contrary direction the other is depressed; when the currents cease, light springs restore the pens to their elevated point. The mode of supplying the pens with ink is as follows:—A reservoir about an eighth of an inch deep, and of any convenient length and breadth, is made in a piece of metal, the interior of which may be gilt, in order to avoid the corrosive action of the ink placed in it; at the bottom of this reservoir are two holes, sufficiently small to prevent, by capillary attraction the ink from flowing through them; the ends of the pens are placed immediately above these small apertures, which they enter, when the electro-magnets act upon them, carrying with them a sufficient charge of ink to make a legible mark on a ribbon of paper passing beneath them. The motion of the paper ribbon is produced and regulated by apparatus similar to those employed in other register or printing telegraphs. These instruments will transmit from 500 to 600 letters per minute through resistance coils."

The transmitter very slightly modified may be used with the usual Morse receiving instruments, and 166 letters per minute were, on a trial, correctly sent with a battery of 120 cells through a circuit of 324 miles of land line, passing from London to Bristol, Bristol to Birmingham, and Birmingham to London. Two distinct earth-plates were used in this trial, and there is reason to believe that the speed was limited rather by the inertia of the moving parts of the receiving instrument than by any inductive influence on the line. The most expert clerk could not transmit more than from 117 to 123 letters per minute. The advantages of the system are pointed out by Professor Wheatstone in the same paper in the following remarks, which are more or less applicable to all good automatic systems:—

"Whatever practical dexterity may be acquired by a voluntary

* "Instead of a voltaic battery, a magneto-electric machine or an electro-magnetic machine may be employed as a source of electric power. In this case, the transmitter and the magneto-electric, or electro-magnetic, machine form a single one, apparently moved by the same power. They are so adapted to each other that the shocks or currents are produced at the moment the pins of the transmitter enter the apertures of the perforated paper."

operator, the result arrived at will be far inferior to that obtained by the automatic process, which is only limited by the rapidity with which the recurring motions of the transmitter can be effected.

"For very considerable distances this rapidity may be limited in conductors subjected to inductive influences by the tendency which rapidly recurring short currents have to coalesce.

"But even if there were no advantage in point of rapidity possessed by the automatic over the voluntary process of transmission, its other advantages would be incontestable. For the profitable working of a telegraphic line, it is necessary that the operator should manipulate as rapidly as is consistent with a correct transmission of the message; it requires great skill to become a proficient in such manipulations, even when the language in which the despatch is sent is quite familiar to the operator; but if he would send a despatch in a language unknown to him, or in cipher, he is obliged to proceed with caution and slowness. In my new system, the prepared messages are transmitted with equal rapidity in whatever language or cipher they may be; and as the perforated bands may be prepared at leisure, and be subjected even to the revision of a corrector, guarantees of accuracy are obtained which cannot be afforded by the system of immediate voluntary transmission. Several clerks will be required to prepare messages for a single telegraphic line in constant activity; but in an economical point of view their time is of far less importance than the time occupied by the transmission of a message.

"Another advantage this system possesses is, that the same prepared message may be transmitted through any number of distinct lines, if not simultaneously, at least in such rapid succession as to be equivalent thereto; and besides, without any fresh labour, the same message may be retransmitted if thought necessary; and service messages in constant use may be preserved for transmission whenever they may be required.

"Were an automatic system generally adopted it might, in many instances, be more convenient to prepare the messages at the offices from which they are sent, the instrument for effecting this purpose being very portable and of small cost. The operations at the telegraph office would in these cases be limited to passing the perforated band through the transmitter at one station and receiving the printed message at the other, the translation, as well as the preparation of the message, devolving on the department of the administration to which it relates."

(To be continued.)

REPORT OF THE DIRECTORS OF THE ATLANTIC TELEGRAPH COMPANY.

The directors herewith present to the shareholders an audited balance-sheet, showing the receipts and disbursements of the Atlantic Telegraph Company from its commencement in 1856 to the end of December, 1863.

During the past year the board has been constantly engaged in completing the financial arrangement for a renewal of this undertaking, and in promoting such investigations and experiments as appeared desirable, in order to secure every practicable improvement in the structure of the future cable.

To advance the latter object, the board issued an advertisement in August last, inviting tenders for a cable suitable for laying across the Atlantic Ocean, and with a view to leave invention entirely unfettered, they abstained from any dictation as to the form or materials to be adopted, merely stipulating for a working speed of eight words per minute.

In reply the board received tenders and numerous specimens of cable and materials. They were at once submitted to the distinguished gentlemen who have throughout so materially assisted the directors by their valuable advice as a scientific consulting committee. This committee, after examining the tenders and causing the specimens to be tested at the works of Mr. W. Fairbairn, unanimously recommended the board to adopt the tender of Messrs. Glass, Elliot and Co., and the general principle of their proposed cable, but advised that before settling the final specification every portion of the material to be employed should be carefully tested, both separately and in combination, so as to ascertain what improvements could be effected either in their quality or in the method of applying them.

Messrs. Glass, Elliot and Co. at once consented to provide material and manufacture specimens, in order to carry out the wishes of the board and of the committee in this respect. Various lengths of cable were tested at the Canal-street works, at Manchester, under the superintendence of Mr. Fairbairn and Mr. Whitworth, and in the presence of the secretary of this company. At the latter place also experiments were separately made upon different qualities of the metal and hemp composing the external protection of the cable. The particulars of all these labours were embodied by Mr. Fairbairn in a statement submitted to his colleagues, whose deliberations thereon resulted in the final report which has been adopted by the board, and is printed herewith for the information of the shareholders, as is also the general specification of the cable, therein unanimously recommended by the committee.

The directors here desire on behalf of themselves and the shareholders to record their feeling of sincere obligation to the members of the scientific committee for their most important and gratuitous services to this undertaking.

The financial position of the company already alluded to, has long and seriously occupied the attention of the board, but they expect now to have the gratification of being enabled to announce at the extraordinary meeting, of which due notice has been given for the 31st instant, that the difficulties of the company in this respect have been removed.

The board regret to report the recent decease of Sir William Brown, Bart., and of Mr. John Watkins Brett, two of the directors of this company.

It is not at present proposed to fill up the vacancies thus created.

The directors retiring by rotation at the present meeting are Mr. George Peabody, Mr. Francis Le Breton, and Mr. John Pender, M.P., all of whom are eligible, and offer themselves for re-election.

The honorary directors in America who retire at the present meeting are, the Hon. George Cartier and the Hon. John Robertson, who, being disqualified, are at present ineligible, and Mr. Watts Sherman and Mr. Cyrus W. Field, who offer themselves for re-election.

The retiring auditor is H. W. Blackburn, Esq., who offers himself for re-election.

This report would have been issued earlier, but for the present non-completion of pending negotiations, the details of which it has been found impossible to conclude in time to lay them before the meeting.

James Stuart Wortley, *Chairman.*
George Saward, *Secretary.*

London, 15th March, 1864.

Report of the Scientific Committee, appointed to consider the best Form of Cable for Submersion between Europe and America.

With a view to determine the most eligible cable for submersion across the Atlantic, we have considered and discussed the results of the numerous experiments that have been made upon the samples of cable supplied to the Atlantic Telegraph Company, in answer to their advertisement, and upon improved specimens prepared subsequently for our examination by Messrs. Glass, Elliot and Co.

We consider the cable No. 46, prepared by Glass, Elliot and Co., to be the one most calculated to ensure success in the present state of our experimental knowledge respecting deep sea cables, and we accordingly recommend the directors to adopt that cable as described in the annexed specification thereof.

We further recommend that the following precautions be adopted during the manufacture by the Gutta Percha Company, and by Messrs. Glass, Elliot and Co. respectively.

That the conductivity of the wire should be determined by the specification at a high standard, to be fixed by the electrical advisers of the company, but at not less than 85 per cent.

That the electrical perfection of the core be determined by the unit system of measurement, and that the standard of the cable should certainly not be below that of the best cable hitherto made.

That the core of the cable be tested under hydraulic pressure, and at the highest pressure attainable in Reid's tanks now at the Gutta Percha Works.

That after submission to this pressure the core be carefully examined, and before it be transferred to Messrs. Glass, Elliot and Co., it be required to pass the full electrical test under water.

That all the tests of the core be made in water, of a temperature of 70° Fahr., and after twenty-four hours' submersion therein.

That the company, as well as Glass and Co., employ proper persons at the Gutta Percha Works to check the electrical tests, and it is

desirable that they should arrive at their results by a different process to that employed by the Gutta Percha Company.

That the completed cable be continuously tested under water at such temperature as the electrical advisers of the company decide on from time to time, and that the company check the tests.

That the joints be tested separately, and that no joint be passed which shows a leakage twice as great as that of a corresponding length of the core.

That careful and frequent mechanical tests be made upon the iron wire and hemp, and that the company, as well as the contractors, keep properly paid and respectable persons on the wire-drawers' premises, as well as at Messrs. Glass, Elliot and Co.'s works, to check the strength and elongation of these materials.

Signed DOUGLAS GALTON.
WM. FAIRBAIRN.
WM. THOMSON.
C. WHEATSTONE.
London, 31st October, 1863. JOSEPH WHITWORTH.

The following is an illustration with a description of the new cable approved of by the scientific committee, and referred to in their Report of the 31st October, 1863 :—

The Conductor consists of a copper strand of seven wires (six laid round one), each wire guaging ·048, or No. 18 of the Birmingham wire-guage, and weighing 300 lbs. per nautical mile, embeded for solidity in the composition known as "Chatterton's Compound." The Insulator consists of gutta-percha, four layers of which are laid on alternately with four thin layers of Chatterton's compound, making a diameter of the core of ·464 inches, and a circumference of 1·392 inches. The weight of the entire insulator is 400 lbs. per nautical mile. The external protection is in two parts; first, the core, surrounded with a padding of soft jute yarn, saturated with a preservative mixture; next to this padding is the protective covering, which consists of ten solid wires of the guage ·095, drawn from homogeneous iron, each wire surrounded separately with five strands of Manilla yarn, the whole of the ten strands thus formed of the hemp and iron being laid spirally round the padded core. The weight of this cable in air is 35 cwt. 3 qrs. per nautical mile, the weight in water is 14 cwt. per nautical mile; the breaking strain is 7 tons 15 cwt., or equal to eleven times its weight per nautical mile in water, that is to say, if suspended perpendicularly, it would bear its own weight in eleven miles' depth of water. The deepest water to be encountered between Ireland and Newfoundland is about 2,400 fathoms, and one mile being equal to 1,014 fathoms, therefore 1,014 × 11 = $\frac{11154}{2400}$ = 4·64, the cable having thus a strength equal to 4·64 times of its own vertical weight in the deepest water.

The following particulars are appended, in order that a comparison may be made between the structure of the new and old cable :—

Conductor, a copper strand, consisting of seven wires (six laid round one), and weighing 107 lbs. per nautical mile. Insulator, gutta-percha laid on in three coverings, and weighing 261 lbs. per knot. External protection, eighteen strands of charcoal iron wire, each strand composed of seven wires (six laid round one), laid spirally round the core, which latter was previously padded with a serving of hemp saturated with a tar mixture. The separate wires were each 22½ guage, the strand complete was No. 14 guage. Weight in air 20 cwt. per nautical mile. Weight in water 13·4 cwt. per nautical mile, or equal to 4·85 times its weight in water per knot; that is to say, it would bear its own weight in a little less than five miles depth of water. Breaking Strain, 3 tons 5 cwt. Deepest water to be encountered, 2,400 fathoms, or less than 2½ nautical miles in depth. The Contract Strain was equal to 4·85 times its weight per nautical mile in water. One knot being in fathoms = 1,014 × 4 = 4 $\frac{4918}{2400}$ = 2,05 times the strength requisite for the deepest water.

ATLANTIC TELEGRAPH COMPANY.

THE seventh ordinary annual meeting of the shareholders of this company was held at the London Tavern, on Wednesday last, the 16th instant, the Right Hon. James Stuart Wortley, chairman of the company, presiding.

The SECRETARY having read the notice calling the meeting, then proceeded, at the request of the chairman, to read the report.

It having been agreed to take the balance sheet as read,

The CHAIRMAN said that it gave him peculiar pleasure, in meeting so many of the shareholders on that occasion, because it convinced him that the interest in their great enterprise was in no degree abated; indeed, it would be strange if it were so; for after what they had already done, they now looked forward with boldness to success, seeing that they had arrived so near to the point of the accomplishment of their great work. He expected to have been able to disclose to them on that occasion important matters in connection with their great undertaking, but owing to unavoidable circumstances he was prevented from doing so, it having been found impossible to bring the details concerning the laying of the cable before that meeting; therefore, when he had gone through the business, he should ask them to adjourn till the 31st of the present month, by which time all the legal instruments would be signed, and he should be able to tell them all about it. He must now congratulate them on the state of their balance sheet, although not what he expected it would have been; still it was better than they had been able to present before, for they had a balance in hand of £61,245, which from fortunate chances they had been able to realize. It was said, that which was one man's meat was another man's poison, and so it had turned out with them, that whilst money had been very scarce, and many things had been restricted in consequence, the directors had been able to realize interest at the rate of from 6 to 8 per cent., and, as was stated in the balance sheet, they had now a balance of £61,245, which was a most satisfactory state of things, but which he hoped would eventually be very largely increased. Some present would do him the honour to remember, that in December, 1862, he stated that they had made arrangements to have the assistance of several scientific gentlemen, to consult and advise as to the best specimen of cable which they could have to carry out the objects of the company, and they had found the greatest willingness on the part of these distinguished gentlemen to assist them in arriving at a proper conclusion. Having advertised in August last, for specimens of cables, and left the manufacturers entirely free to adopt any form or materials they might please, merely stipulating for a speed of eight words per minute, they received seventeen specimens and tenders, through all of which these gentlemen very carefully went, and he was sure that when he informed them that the council consisted of Captain Galton, in connection with her Majesty's government, Mr. W. Fairbairn, Professor Thomson, Professor Wheatstone, about the oldest electrician of the day, and Mr. Whitworth, whose name was a household word, they would feel certain that great care had been taken in arriving at a conclusion. It had often been a reproach of scientific men that they rode their own hobby, to the exclusion of all others, and it was often too true; but it had not been so in this case, and after a great deal of gratuitous labour, careful deliberation and testing, these five gentlemen came to the unanimous resolution, that out of the seventeen specimens sent, that of Messrs. Glass & Elliot was the most suitable, and the directors thereupon resolved to have it; at the same time determining, previous to a final arrangement, to have each portion of the material employed carefully tested, so as to ascertain whether any improvements could be made either in their quality or the mode of applying them, all of which took place under the superintendence of Messrs. Fairbairn and Whitworth. As the contract is not quite completed, the directors did not feel at liberty to go further into particulars; they expected it to be signed in a few days, however, as it was now in the hands of the lawyer to complete, but as there might be some little delay in this, as lawyers were not proverbial for punctuality in these matters, they proposed to meet again on the 31st instant, in order that every thing might be certain of completion, when the directors again meet the shareholders. There was one thing he must explain, although perhaps it might be hardly necessary: some of them had by that time received a note, informing them of a call of 30*s*. per share. It was on account of the perfect confidence they have in the success of their undertaking, that the directors had made this call. They had been reproached in some instances, by being asked, why they did not call their money in, so as to set their affairs in a proper position; but it was not made payable till the 7th of April, which would be subsequent to the meeting, at which he hoped to show them that their financial difficulties had been overcome. He was not aware that he had any thing more to dwell upon, he would merely urge upon them all, as far as their engagements would permit, to be present on the 31st instant, and to bring all their friends with them who take an interest in the company, as matters of importance will be communicated on that occasion. He would not sit down without saying how grateful he felt to his colleagues for the kind assistance they had rendered him throughout the year, for at one time his health was such as rendered him totally incapable of attending to his duties; he was thankful, that now his health was restored, and he should devote himself anew to the affairs of the company; the deputy chairman's labours had been unwearied, and to him and his friend Mr. Cyrus Field, who had crossed the Atlantic thirty-one times in the interests of the company, he felt deeply indebted. He was proud to meet on the past evening, collected around the tables in

that room, a large number of distinguished persons, merchants and capitalists, who had assembled to do honour to that gentleman. It was peculiarly gratifying to see an American so surrounded, to celebrate the approaching completion of their noble undertaking. He would now move, "That the report now read, and the statement of accounts thereto annexed, be and they are, hereby received and adopted by this meeting."

CURTIS M. LAMPSON, Esq., Vice-Chairman, having seconded the proposition, it was put to the meeting and carried unanimously.

In reply to a question, the CHAIRMAN stated that the negotiations for the cable, for the laying, and for the ships would all be included in one contract.

The CHAIRMAN then proposed, "That the directors retiring by rotation at the present meeting, viz., Mr. George Peabody, Mr. Francis Le Breton, and Mr. John Pender, M.P., be re-elected directors of the Atlantic Telegraph Company," which having been seconded by Mr. EDWARD CROPPER, was put to the meeting and carried unanimously.

The CHAIRMAN next proposed "That the Honorary American Directors retiring by rotation at the present meeting, viz., Mr. Watts Sherman, of New York, and Mr. Cyrus W. Field, be re-elected Honorary Members of the Atlantic Telegraph Company," remarking that a greater loss could not happen to the management of the company than to be without the assistance and advice of his friend Mr. Cyrus Field at their board.

Captain HAMILTON having seconded the proposition, it was submitted to the meeting, and carried unanimously.

The CHAIRMAN then proposed, "That Mr. Henry Webster Blackburn be re-elected auditor to the Atlantic Telegraph Company."

The motion was seconded by Mr. FRANCIS LE BRETON, and carried unanimously.

C. M. LAMPSON, Esq., then moved, "That this meeting stand adjourned until the 31st instant, to be preceded by a Special General Meeting, at a quarter before one o'clock on the same day."

Mr. LE BRETON seconded the motion, which, having been put to the meeting, was carried unanimously.

The thanks of the meeting to the Right Hon. James Stuart Wortley, for presiding on the occasion, having been unanimously accorded, that gentleman briefly acknowledged the compliment, and the meeting adjourned.

THE ROYAL SOCIETY.

GENERAL SABINE, the President of the Royal Society, gave his first *conversazione* this season, on Saturday evening, at the apartments of that learned society, at Burlington House, Piccadilly. There was a very large attendance of fellows and friends connected with the different scientific institutions in the metropolis, together with several foreign celebrities in science. All the saloons thrown open were tastefully adorned by some of the choicest trees, plants, and flowers, lent by the Royal Botanic Society. The suite of apartments was furnished for the occasion with a large collection of philosophical apparatus, instruments, and models of machines in operation of more than ordinary merit, besides numerous sculptures, paintings, drawings, maps, carvings, and other works of art.

These included electro-magnetic telegraph semaphores, in operation, as used in train signalling on the South-Eastern Railway, manufactured by Messrs. S. W. Silver and Co., of Bishopsgate Within; Mr. J. Browning's improved spectroscopes and aneroids, and a new liquid compass, with 11-inch aluminium card, the largest instrument of the kind as yet made; Professor Stokes's handy spectroscopes for examination of liquids; Professor Clark Maxwell's electric bobbin, with vibrating commutator, for determining the declination and dip of the magnetic force; Professor W. Thomson's new electrometer, and reflecting galvanometer, and new spectroscopes, by Elliott Brothers; Mr. Fleeming Jenkin's frictional governor, by which uniform rotary motion can be maintained in wheelwork, driven by varying weights, or subject to varying resistance; microscopes, by Smith and Beck, Powell and Lealand, Murray and Co.; illustrations of M. Vial's process of instantaneous engraving, exhibited by Messrs. Davies and Hunt; "The First Sorrow," a painting, by Sant, A.R.A.; bronzes and mediæval ivories, lent by E. W. Cooke, R.A.; busts by Woolner, Herr Boehm, and Alexander Munro; lilybud, in marble, by E. Davis; plaster models; "The Secret," by Raemacker, and "A Mother's Love," by E. Landseer: statuette of Thackeray, in terra cotta, Boehm; specimens of photo-sculpture, exhibited by Mr. Claudet; statuettes, "Boys at Play," J. Durham; crayon portraits, by G. Richmond; models of the engines of the Agincourt and Octavio, Messrs. Maudslay and Co.; model of the Sultan's yacht Taliah, Mr. J. d'A. Samuda; drawings and plans of the Thames Embankment, lent by the Metropolitan Board of Works; specimens from caves in France, illustrative of the industry of the stone age at the reindeer period, imbedded in breccia, with bones of reindeer, aurochs, and horse, exhibited by Messrs. Lartet and Christy; pigmy fossil elephant of Malta, *Elephas Melitensis*, and reindeer bones of colossal size, from the Gower caves, exhibited by Dr. Falconer; and Gisborne's patent electrical and mechanical engine and steering instruments, giving accurate and instantaneous communication between the captain, the engineer, and the helmsman, exhibited by Messrs. Silver and Co.

THE UNITED KINGDOM TELEGRAPH COMPANY.—The wires of this company were open to Huddersfield in the week, and it is expected that several additional stations will be opened in the course of the month.

CORRESPONDENCE.

TELEGRAPHIC FEATS.

To the Editor of the TELEGRAPHIC JOURNAL.

SIR,—As my last arrived too late for insertion, please cancel it, and substitute this one. I must apologise for its length—perhaps the interest which the subject evidently creates amongst your readers will compensate for the trouble I am giving you. I had relinquished the idea of again appearing in your columns until I saw, to my surprise, that I was charged with representing the speed of the electric present single needle at 15 words per minute. I have it 25 in my copy of that letter—the error has been inadvertently made in the hurried transcription from my rough copy, and from a category I have of the respective speeds of a variety of old and new instruments. I had, just previous to writing that letter, been a witness to the trial of the single needle electric.

It has been wisely remarked that every expert clerk has an affection for, and is prejudiced in favour of, the instrument he works. This is true almost without exception, and especially when applied to the Electric staff. Out of the many whom I have encountered only one acknowledged the supremacy of the Magnetic Company's single needle; the others adhere tenaciously, and in defiance of facts and vision, to their own opinions. The Magnetic Company have been undervalued, their circuits shortened, their instruments slighted. Nothing magnetic will digest on the stomach of an Electric. There is no occasion for this individual rivalry.

Now, however, is the time to establish, by statement and proof, the superiority of the bell instrument over that of the electric systems, and I thank the two correspondents of last week for their assistance.

I dispute the statement made by "Bon Accord," that the Queen's Speech was transmitted from Aberdeen to Inverness at the rate of 30 words per minute, not accounting for stoppages by minor stations on same circuit. If there were any stoppages that speed was unattainable.

At first I gave "Old Morse Clerk" credit for care and discernment, but a closer scrutiny (he first turned critic) convinces me otherwise. In his first letter he says a uniform rate of 36 words per minute could be maintained on the Morse. In a contemporary journal, it is given, from authority, that one of Bright's speeches, containing 25,000 words, was despatched by a Morse at an average rate of 22 words per minute. This was a feat. Their feats now are no better, and yet he "will not yield the palm in point of speed to bells."

He doubts whether 19 French words per minute could be sent for any length of time on bells. In his next he turns critic, says I condemn the Morse, asks a question illogically and unfairly put, fears that I never saw a Morse instrument, and does not understand the term "yarn" in Morse phraseology. He says a message can be arrested on the instant, appeals to visitors, who are no judges of the *comparative speeds* of instruments, and, in face of an explanatory paragraph in my last, asks why, instead of averaging 35 words a minute the bells don't always attain 50, and closes his letter with a deduction that mine was not impartial, and did not contain facts.

It would take another column of paper to examine these points severally. Will the interested reader go through them again, and notice every sentence? He must concede that they answer themselves, with the exercise of a little judgment. However ignorant "W. H. N." may be of the Morse he is scarcely so inconsistent as his friend at Dover is with the bells; and he knows that a "yarn" means the array of dots required to be given by a Morse sender wishing to correct himself; that a sender cannot be instantly arrested, else why that rule "to stop at the end of every address, &c., in messages, and periodically in news."

I agree that the contest lies between the bells and Morse. The recording properties of the latter however, do not, on home circuits, compensate for the extra speed, the simplicity, and cheapness of the former, the clerk's writing being a sort of record, and all that is required. In point of accuracy they are, I think, about equal.

The electric single needle, when classed in such company, hardly deserves mention, and the double needle is actually, when much used, slower than the Morse, owing to the tiring manipulation. With the speech mentioned before a contest ensued between the two (*see* paper). The double needle very fast at first; at end of half hour both equal; at finish of speech printing much the quickest—average rate of printing, 22 words per minute. A bell clerk would despise this speed.

Taking all the minute particulars into consideration, the bell deserves, and ought, and I hope will have the supremacy amongst the instruments used by the two large companies. I do not admire that principle which would keep in oblivion the fame and recommendations of an instrument which is likely to effect such improvement and good in the mercantile world because it is not owned by the community of which such thinkers form a part.

I refer my opponents to page 126, in No. 12 of this journal, on bells, and will disappear from the scene, after appending this quotation:—"Sir W. O'Shaughnessy, in 1861, reported that the substitution of an acoustic for the Morse tape system effected a saving of £3,000 per annum on the Indian lines, and was accompanied with twofold accuracy. The British and Irish Magnetic Telegraph Company are of opinion that the acoustic system saves them several thousands a year."—I am, Sir, yours truly,

W. H. N.

Stockton, March 16, 1864.

TELEGRAPH CLERKS' PROVIDENT FUND.

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—When I accepted the post of chairman at the Magnetic employés' meeting, I little expected it would be the means of involving me in journalistic warfare. However, as such appears to be the case, I must e'en take up the gauntlet, and do my best for those whom I have the honour to represent.

Your correspondent, "A Shareholder," wished to know "a few of the arguments adduced at our meeting, and the principal objections we had to the Telegraph Clerks' Provident Fund." My reply, giving that explanation, has elicited letters from three correspondents, signing themselves "G. Benson," "A Shareholder," and "One of the Least." The first of these gentlemen, after highly eulogising the merits of Miss Oppenheim, says, "In round calculation, the sum of 3d. per week is demanded—not a very exorbitant amount—for which trifling payment we receive, in cases of illness, a weekly allowance of 10s., *and in that of temporary disorder, the best medical advice from a physician, together with assistance from the fund.*"

Mr. Benson has either not yet read the rules, or wholly misunderstood those he has read—as, if he turns to rule 9, he will find these words:—"But no person shall claim pay for any slight accident or illness, which neither confines the patient to the house, requires extra diet, nor causes him or her to experience pecuniary loss."

So much for Mr. Benson's conclusions as to *temporary disorder.*

Again, he says, "It ought not to be grudged that some benefits should fall to the other side. And, notwithstanding the society's late formation, its sick-list is already large, and much greater than was at first expected." Is Mr. Benson financially interested in the fund? As, if so, we may draw our own conclusions as to the benefits he would wish the fund to experience—if not, I should feel obliged if he will explain the benefits he wishes not to be grudged falling *to the other side.* I was not aware, *and certainly do not believe,* the fund was established to benefit its promoters. Your correspondent evidently left his spectacles at home, and laboured under a defective eyesight, when he read the "Report of the Telegraph Clerks' Provident Fund," or he would have seen there are only two members on the sick-list, and that the round numbers should be 4d., instead of 3d., for assurance of 10s. per week during sickness, viz.—3½d. subscription, ½d. per week towards management: this, with incidental fines, &c., would, no doubt, amount to 4d. per week. If your correspondent refers to the last paragraph in my former letter, he will find I did not say the meeting disagreed with the payments: far otherwise—they wished for "*higher subscriptions.*"

With reference to "Mr. Samuel Gurney, Sir Morton Peto," &c., I much question whether any of the patrons or patronesses have even glanced at the rules: they have merely come forward in a just cause—viz., relief to the telegraph clerks—not even waiting to study the technical points introduced into the rules of the fund.

As "A Shareholder" so nearly agrees with my views, I have very little to offer in reply to his second communication, and will content myself by saying, it would be very disagreeable for those clerks living 200 or 300 miles away from home, to have to produce their certificates of birth or baptism, for which they would most probably have to pay the fee of 2s. 6d. It is certainly necessary to produce those documents when insuring on life, but I cannot see that it is at all essential when assuring for sick pay.

As to the rule requiring the magistrate's signature to the medical certificate, I think that might be modified, by making it necessary to obtain the signature of the district superintendent of the company to which the clerk belongs.

"One of the Least"—the writer of the concluding letter in your last week's Journal—has evidently mistaken the reason of my writing my previous letter, and has therefore applied his remarks to me personally.

As he has thought fit to title me "the self-imposed champion of our oppressed and suffering sisterhood," I must, in proof of my determination to uphold that championship, say that it would be mean and paltry in the extreme, for any male subscriber to speak of "injustice," if the fund should ever be called upon to grant sick pay to a female member when visited by illness consequent upon maternity.

The female members might, with the same grace, plead "injustice," when called upon to subscribe for sick pay to a male member suffering from an accident through "cricket," or any other manly sport in which they, the female members, are not in the habit of indulging.

I cry shame against the man who would say it was unfair to allow sick pay, or a certain sum, to the female clerks, under the circumstances mentioned.

"One of the Least" says, "that by some clerical error, the word 'unlawful' has been omitted before 'sports.'" Whether or not your correspondent framed the rules, I cannot say; but as I am unaware of any *unlawful* manly sports or games, I am at a loss to imagine how that word can materially alter the rule or point at issue. Again, he says, "baptismal certificates are not insisted upon, unless some reasonable doubt is entertained of a candidate's statement of age." I do not find these particular words in the book of rules issued by the fund—and here I may mention, the original prospectus was discussed *as it stood,* in its several sentences, and not as altered by your correspondents, who appear to add to those rules the words, they think, are required.

When I referred to the connection of the "Telegraph Clerks' Provident Fund" with the "District Company," I meant merely to call attention to the fact, that Miss Oppenheim, being secretary of the first and superintendent of the latter, might naturally be expected to exercise more influence over her own clerks, being immediately connected with them than over clerks of other companies, and that it was curious she had been unable to obtain more than sixty or seventy members out of 150 to 200 clerks employed by the London District Telegraph Company.

I perfectly agree with all that has been said upon co-operation; and for my part, if I considered the rules of the "Telegraph Clerks' Provident Fund" at all conducive to the clerks' benefit, I would do all in my power to get the Magnetic Company's employés to become members, which, I am convinced, they would do, because like myself they are all "*champions of our suffering sisterhood,* and would only be too glad to belong to a society where they would be brought into the company of their fair sister-clerks, thus, mayhap, securing a foundation for the realisation of one of those "happy events" which would lead to "the necessity of forming a special subscription" which "One of the Least" appears to advocate.

I will conclude with one more question, which, I hope, will finish this useless controversy. If it was known a society was about to be formed for the relief of telegraph clerks, why did not the promoters call a special meeting of that particular body, and submit to that meeting the proposed rules and regulations *before being sent to the Registrar to be certified,* and not call a meeting after they are signed and cannot easily be altered?

This is what should have been done, and which would have prevented all discussion and unnecessary correspondence.

Heartily thanking "One of the Least" for his supplying me with a title
I am, Sir, yours very faithfully, GEO. C. NEWBURY,
"*Champion of our suffering sisterhood.*"

58, Threadneedle-street, March 16, 1864.

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—Mr. Benson, of the Submarine Company, having taken upon himself the championship of the "Provident Fund," will you kindly allow me to ask him, through your columns, to what cause we must attribute the fact of his not having joined it?—Yours faithfully, — — - - — —.

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—Would any practical telegraphist please inform me, if on a wire of 180 miles in length, with a station at each end, there is a loss about twenty miles from one end of it, which station would get the strongest signal provided the battery power at each end was alike? My idea is, that the station nearest the fault would get the strongest signals.—Yours, &c. K. H.

TELEGRAPHIC NEWS.

OTTRANTE AND AVELONA CABLE.—It is determined to complete the submergence of the above cable in the month of April next, when it is to be hoped that the fine weather which generally exists between those coasts about that period of the year will enable those engaged to lay the remainder of the cable successfully.

A LIGHT-SHIP FOR THE ATLANTIC.—A project of a novel and important character has been for some months past under discussion; and we are informed that a company is now in course of formation, with a view to place the proposal in a practical shape. It is intended to station, fifty miles west of Scilly, a ship bearing a floating light, containing stores of provisions, and connected by an electric cable with the shore. It is considered that thus early news may be conveyed, homeward ships may receive their orders whilst at sea, and much suffering, privation, and loss of life be prevented. The work is to be carried out by Moore's patent for an improved method of anchoring ships, and attaching electric cables. The idea is seriously entertained, and, if carried out, might prove of much commercial value. We should be sorry to pronounce it to be impossible, or to throw an obstacle in the way of its accomplishment; but if Moore's patent can securely moor a vessel amid the wild waves of the broad and deep Atlantic, and can secure easy communication at all times with passing ships and with the shore, the invention must be ranked as one of the most marvellous of the age.

THE MALTA AND ALEXANDRIA CABLE.—The steamer Fanny Lambert returned to Malta on the 23rd ult., having been compelled so to do in consequence of some displacement of the cable, caused by stormy weather which she unfortunately met with. H.M.S. Surprise called in at Benghazi on Saturday afternoon; but, after two hours' stay, left for Tolmeitah, in the vicinity of the locality where the fault is supposed to exist, and where the Fanny Lambert expected to meet her on the following Wednesday morning, for the purpose of restoring telegraphic communication on the Alexandria-Benghasi section of the line. We are glad to state that the Fanny Lambert has made good all the derangements which occurred to the cable on board during the late trip, and left this morning for Tolmeitah. It is very satisfactory to know that not the least damage occurred to the cable or machinery on board this vessel, and that confident hopes are entertained of a speedy restoration of this telegraphic line. The greater the difficulties that are overcome, the greater will be the merit due to all members of the expedition.

THE MALTA AND ALEXANDRIA CABLE.—It is reported that intelligence is hourly expected of the complete restoration of the Malta and Alexandria cable. We sincerely trust that the report will prove correct, as this line of telegraph is of the utmost importance to the commercial world.

THE PERSIAN GULF SUBMARINE CABLE.—No further information has reached us than we have already published, of the progress which has been made in laying the remaining sections of the above cable. The next Bombay mail is due, we believe, next Monday; but should success attend the endeavour to submerge the sections to Shat-al-Arab at the head of the Gulf, intelligence may reach us at any moment, as there are land lines from thence to Constantinople and England. Some doubts seem to exist as to the condition of the land lines between Bussorah and Bagdad; and if not available, we must look for further information with respect to the operations in the Persian Gulf per the Bombay mail, as already observed.

THE MEASUREMENTS OF THE VELOCITY OF PROJECTILES.—Mr. George E. Newman, of the Electric and International Telegraph Company, Manchester, has contrived an apparatus for ascertaining the velocity of projectiles, which was put into practical test at Liverpool during the last week. It has been very highly spoken of in the *Times* and other journals for its efficiency for the purpose.

THE ELECTRIC AND INTERNATIONAL TELEGRAPH COMPANY obtained leave from the Grand Jury of the county Down, on Wednesday, to lay wires along the high road. The agent of the company stated that they were going to carry their line to the seaboard, and thence across to the Scottish coast.

DR. ESSELBACH.—We insert the following extract from a private letter received from Bombay, communicating the sad and melancholy death of Dr. Esselbach. The deceased had long been connected with telegraphy, both in England and abroad, and was distinguished for his profound mathematical acquirements and electrical knowledge. "It may be that I am the first to convey to you the following sad intelligence. Dr. Esselbach, who, from the outset, took a very lively interest in the laying of the cable, had a fever for three days, and (as we suppose) in the delirium of the fever put an end to his own existence, by jumping overboard. At present we know very little of the circumstances, our information being derived exclusively from a telegram from Col. Stewart, announcing the fact. Dr. Esselbach, whose acquaintance I had but just formed, seemed to be a gentleman of a particularly amiable disposition, and possessed of a very delicate nature. His health, when in Bombay, was apparently good. His untimely death has cast a gloom over us all, and we are, at present, entirely uninformed as to what changes in the staff may result from it. The first portion of the cable, I am happy to say, has been successfully laid. The telegram, announcing this, arrived scarcely twenty-four hours before that intimating the event I have just mentioned. It is not improbable that the fever may have been increased by the excitement attending this. Since then, we are informed that a further section of the cable has been laid. This nearly completes the line between Guadal or Guadur, and Cape Mussendom. The Tweed has arrived here, and will join the expedition as soon as the stores are removed, and the cable machinery fitted up, work which is now being rapidly proceeded with. Of the Assaye and Amber Witch we have heard nothing; every day we look for their arrival. The Tweed brought us Mr. H. amongst others, whom the voyage appears to have suited exceedingly; also Mr. M., who appears well in health. P.S.—The Assaye has just arrived, so that, excepting the Amber Witch and Cospatrick, the whole of the ships are here."

A COMPANY has been formed for effectively carrying out and extending Bonelli's Electric Telegraph. The capital is to be £250,000, of which £25,000 forms the original capital of the company. Under the present arrangement there will be a further issue of £225,000, in 22,500 shares of £10 each, the deposit to be £1 on application, and £1 on allotment. A line is already established between Manchester and Liverpool, the working of which is stated to have exhibited practically and commercially the great excellence of Bonelli's system, and the directors, whose names and position are recognised, appear determined to give it full scope. Arrangements have, therefore, been made to acquire the entire patent-right for the United Kingdom, as well as to meet all the remaining expenditure necessary to establish operations on the proposed enlarged footing. It is intended to reduce the tariff to a uniform rate of sixpence per ordinary message of twenty words, while full rapidity, correctness, and punctuality will be attained. The typo-electrical instrument possesses a variety of advantages, among the foremost of which may be enumerated the printing of each message in the very act of transmission, and the celerity with which any extent of communications may be forwarded. Certainly the experiments made at the office show the effective nature of the working, and the valuable nature of the invention now it is to be brought into active use. Almost every department of business or profession that has anything to do with telegraphy will, it is asserted, benefit by the change; and, therefore, under the circumstances, the extension of the principle deserves to be supported.

THE PROSPECTUS of Silver's India-rubber Works and Telegraph Cable Company (Limited), has been issued, and the undertaking appears to be placed on a very safe foundation. The property is well known, and the direction comprises names that will be readily recognised. The capital is to be £500,000 in 10,000 shares of £50 each, of which 5000 will only now be issued. £2 per share is to be paid on application and £3 per share on allotment, of which a considerable proportion have already been subscribed for. There seems to be no doubt but that the business of the works at Silvertown has rapidly expanded, and that the operations carried on may be conducted with considerable profit, while the locality in which they are situated is favourable for the home and foreign trade. An important feature in the arrangement is that Messrs. Silver and Co. will still remain identified with the operations, and that their experience, skill, and influence will be used for the benefit of the company. Their confidence in its perfect success will, it is believed, be appreciated when it is stated that out of the amount to be paid for machinery and plant, stock, and book debts—say £100,000—they are willing to receive one half in shares and the remaining half in cash and debentures bearing interest at 5 per cent. For the freehold land and works, which are to be valued, they will also receive the larger portion in similar debenture.

TO CORRESPONDENTS.

*** The *Telegraphic Journal* will be published on Thursday next week.

THE ELECTRIC AND INTERNATIONAL TELEGRAPH COMPANY'S DRAMATIC CLUB.—Account of performance unavoidably deferred until next week.

OLD DOUBLE NEEDLE AND MORSE CLERK.—Your communication arrived too late for insertion this week.

The *Telegraphic Journal* can be had of Messrs. SMITH & CO., Strand; Messrs. DAWSON & CO., Cannon-street, E.C.; Messrs. KENT & CO., Paternoster-row, London. Messrs. HEYWOOD & CO., Manchester; at the various railway stations; and of all news-agents, &c., &c.; or it can be supplied, if preferred, direct from the Office on the following terms:—

	s.	d.
Quarterly	4	4
Half-yearly	8	8
Yearly	17	4

TO ADVERTISERS.

Clerks, assistants, manipulators, and instrument makers, seeking employment, &c., will find the *Telegraphic Journal* a ready means of making known their requirements.

Single Advertisements from the country must be accompanied with stamps in payment.

Advertisements must be delivered to ensure insertion before SEVEN O'CLOCK on Thursday evening in each week. The charges for Advertisements are—

THE ATLANTIC TELEGRAPH.

THE great project which has now for many years engaged the attention of scientific and commercial men appears to rapidly approach realization. As to the practicability of deep sea telegraphy there exists happily no difference of opinion among our leading engineers and electricians. The valuable and important improvements which have of late been effected in the preparation and manufacture of insulating materials, and in the application of external strength, combined with enlarged experience, cannot fail to render future operations in deep sea telegraphy eminently successful and very profitable. When we contemplate the magnitude of the present undertaking, the vast interests which it is sought to strengthen and consolidate, it is impossible to exaggerate the importance of establishing telegraphic communication between the English and American shores. The incalculable advantages already derived socially, commercially, and politically by the extension of submarine telegraph lines become daily and hourly more appreciated, and render any temporary interruption in their working more keenly felt and deplored. In the effort now about to be made to submerge an Atlantic cable, the Company has sought the opinion and advice of men of the highest scientific attainments and practical experience, and who have been engaged in making numerous experiments, with the view of ascertaining the best form of cable, both as to its transmitting capacity and strength, the great object to be attained in the latter case being a minimum of extension and the maximum of breaking weight during the process of laying the cable. The Scientific Committee, out of the seventeen specimens received, have selected a cable designed by Messrs. Glass, Elliot, & Co., an engraving and comparative description of which will be found on the next page. The Committee, which consisted of the following distinguished *savans*—Capt. Galton, F.R.S.; W. Fairbairn, F.R.S.; W. Thomson, F.R.S.; Charles Wheatstone, F.R.S.; and J. Whitworth, F.R.S., state in their report that, with a view to determine the most eligible cable for submersion across the Atlantic, they had considered and discussed the results of numerous experiments that had been made upon the samples of cable supplied to the Company in answer to their advertisement, and upon improved specimens prepared subsequently by Messrs. Glass, Elliot, & Co., and that they considered the cable prepared by that firm to be the one most calculated to ensure success in the present state of our experimental knowledge respecting deep sea cables; and they accordingly recommended the Directors to adopt that cable. They further recommend that the following precautions be adopted during the manufacture by the Gutta Percha Company and by Messrs. Glass, Elliot, & Co. respectively, namely, that the conductivity of the copper strand be determined by the specification at a high standard, to be found by the electrical advisers of the Company, but not at less than 85 per cent.; that the electrical perfection of the core be determined by the unit system of measurement, and that the standard of the cable should certainly not be below that of the best cable hitherto made; that the core of the cable be tested under hydraulic pressure, and at the highest pressure attainable in Reid's tanks, now at the Gutta Percha Company's Works; that after submission to this pressure the core be carefully examined, and before it be transferred to Messrs. Glass, Elliot, & Co., it be required to pass the full electrical test under water; that all the tests of the core be made in water of a temperature of 70° Fahr., and after twenty-four hours submersion therein; that the Company, as well as Glass, Elliot, & Co., employ proper persons at the Gutta Percha Company's Works to check the electrical tests, and it is desirable that they should arrive at their results by a different process to that employed by the Gutta Percha Company; that the completed cable be continuously tested under water at such temperature as the electrical advisers of the Company decide on from time to time, and that the Company check the tests; that the joints be tested separately, and that no joint be passed which showed a leakage twice as great as that of a corresponding length of the core; that careful and frequent mechanical tests be made upon the iron wire and hemp, and that the Company as well as the contractors keep properly paid and respectable persons on the wire drawers' premises, as well as at Messrs. Glass, Elliot, & Co.'s Works, to check the strength and elongation of these materials.

The very efficient and stringent precautionary measures, carried out in their integrity, must result in the construction of a cable of the most perfect description in every respect. The advantage of such tests, carefully conducted and recorded, will prove at all times most valuable in the electrical management of the cable when submerged and in actual operation.

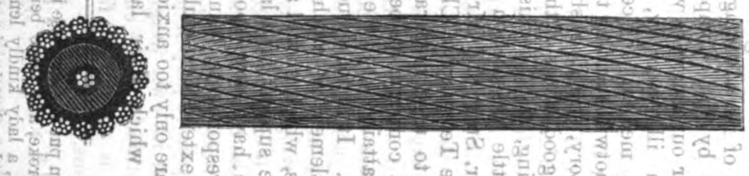
The experience derived in the submersion of the Toulon and Algiers deep sea cable has to a considerable extent influenced the decision of the Committee and the designers in the selection of the form of the new cable. No difficulty was experienced in paying out the above mentioned cable, and the electrical tests showed that its submersion was effected without in the least affecting injuriously its insulation. The form of cable adopted is thus described:—The conductor will consist of a copper strand of seven wires (six laid round one), each wire gauging ·048 or number 18 of the Birmingham wire gauge, and weighing 300 lbs. per nautical mile, embedded for solidity in the composition known as "Chatterton's Compound." The insulator is to consist of gutta percha, four layers of which are to be laid alternately with four thin layers of the above-named compound, making the diameter of the core of ·464 inches, and a circumference of 1·392 inches. The weight of the entire insulator is to be 400 lbs. per nautical mile. The external protection is to be in two parts; first, the core surrounded with a padding of soft jute yarn, saturated with a preservative mixture; next to this padding is to be the protective covering, to consist of ten solid wires of the gauge ·095 drawn from homogeneous iron, the same as now used by Whitworth in the manufacture of his celebrated guns, each wire surrounded separately with five strands of Manilla yarn, the whole of the ten strands thus formed of the hemp and wire to be laid spirally round the padded core. The weight of the cable in air will be 35 cwt. 3 qrs. per nautical mile; the weight in water will be 14 cwt. per nautical mile; the breaking strain will be 7 tons 15 cwt., or equal to eleven times its weight, per nautical mile in water; that is to say, if suspended perpendicularly from the stern of the vessel, it would bear its own weight in eleven miles depth of water. The deepest water to be encountered between Ireland and Newfoundland is about 2400 fathoms, and one mile being equal to 1014 fathoms, therefore—

$$1014 \times 11 = \frac{11{\cdot}154}{2400} = 4{\cdot}64$$

the cable having thus a strength equal to 4·64 times of its own vertical weight in the deepest water.

Perhaps not the least important feature in connection with the Atlantic Telegraph Company is the proposed employment of the Great Eastern, with its ample accommodation, in laying down the cable. The adaptability of the great ship for the conveyance and submersion of deep-sea telegraphic cables has long been recognised by nautical men; one great advantage being that the whole cable can be conveniently stowed in water tanks between her ample decks, and we can only reiterate our firm opinion as to the ultimate success of deep-sea telegraphy.

To enable our readers to compare the cable submerged between Ireland and Newfoundland by the Atlantic Telegraph Company in 1858, and the cable now being manufactured for the same Company by Messrs. Glass, Elliot, & Co., we insert a drawing and section of each cable exact as to size and detail:—



OLD ATLANTIC CABLE, 1858.

CONDUCTOR—A copper strand, consisting of 7 wires (6 laid round one), and weighing 107 lbs. per nautical mile.

INSULATOR—Gutta-percha laid on in three coverings, and weighing 261 lbs. per knot.

EXTERNAL PROTECTION—18 strands of charcoal iron wire, each strand composed of 7 wires (6 laid round one), laid spirally round the core, which latter was previously padded with a serving of hemp saturated with a tar mixture. The separate wires were each 22½ gauge, the strand complete was No. 14 gauge.

WEIGHT IN AIR—20 cwt. per nautical mile.

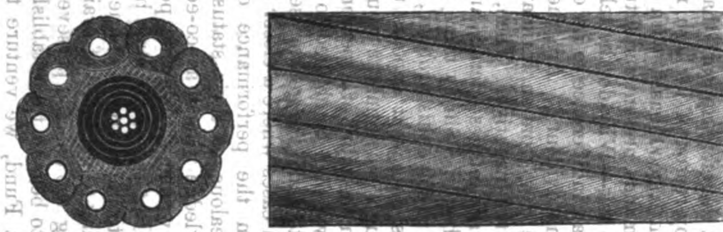
WEIGHT IN WATER—13·4 cwt. per nautical mile, or equal to 4·85 times its weight in water per knot—that is to say, it would bear its own weight in a little less than 5 miles depth of water.

BREAKING STRAIN—3 tons 5 cwt.

DEEPEST WATER TO BE ENCOUNTERED—2,400 fathoms, or less than 2½ nautical miles in depth.

THE CONTRACT STRAIN was equal to 4·85 times its weight per nautical mile in water.

ONE KNOT, being in fathoms $=1{,}014\times 4=\frac{49170}{2400}=2\cdot05$ times the strength requisite for the deepest water.



NEW ATLANTIC CABLE, 1864.

CONDUCTOR—Copper strand, consisting of 7 wires (6 laid round one), and weighing 300 lbs. per nautical mile, embedded for solidity in Chatterton's compound. Gauge of single wire ·048 = ordinary 18 gauge. Gauge of strand ·144 = ordinary No. 10 gauge.

INSULATION—Gutta-percha, 4 layers of which are laid on alternately with 4 thin layers of Chatterton's compound. The weight of the entire insulation, 400 lbs. per nautical mile. Diameter of core, ·464; circumference of core, 1·392.

EXTERNAL PROTECTION—10 solid wires of the gauge ·095 (No. 13 gauge), drawn from Webster & Horsfall's homogeneous iron, each wire surrounded separately with 5 strands of Manilla yarn saturated with a preservative compound, and the whole laid spirally around the core, which latter is padded with ordinary hemp saturated with preservative mixture.

WEIGHT IN AIR—35 cwt. 3 qrs. per nautical mile.

WEIGHT IN WATER—14 cwt. per nautical mile, or equal to 11 times its weight in water per knot—that is to say, it will bear its own weight in 11 miles depth of water.

BREAKING STRAIN—7 tons 15 cwt.

DEEPEST WATER TO BE ENCOUNTERED—2,400 fathoms, or less than 2½ nautical miles in depth.

THE CONTRACT STRAIN is equal to 11 times its weight per nautical mile in water.

ONE KNOT, being in fathoms $=1{,}014\times 11=\frac{11154}{2400}=4\cdot64$ times the strength requisite for the deepest water.

TELEGRAPH CLERKS' PROVIDENT FUND.

WHEN friends get into controversy, one of the greatest drawbacks to a solution of the question in dispute is the hesitation manifested by the disputants in the honest and full expression of their sentiments; this is especially the case in the discussion of social matters on which there simply exists a diversity of opinion. It has been remarked that the use of language is to enable man to disguise his thoughts, and we fear that several of our correspondents, in their communications on the subject of the Telegraph Clerks' Provident Fund, have urged every objection to the institution but those which actually determine their conduct in relation thereto. Like all special provident or insurance organisations, this Fund has a particular class of lives to insure, and the managing committee appear to have acted with wisdom in adopting the recommendations of an eminent actuary, and fixing the scale of premiums in excess of the general rate, thereby ensuring the stability of the institution, and guaranteeing to the member, as far as practicable, the benefits for which he subscribes. It happens too frequently that the projectors of benefit clubs fail to exercise necessary caution, and by offering inducements to all classes of lives, and transacting business at too low a rate of payment, jeopardise the character of the institution at the outset, and eventually create distrust in the minds of members, who, after having paid their subscriptions for many years, are not unfrequently deprived of the benefits on which they had depended by the collapse of the society. The evil does not end here, for persons once subjected to these losses, distrust their fellows, lose faith in all righteous principles, and relapse into habits of improvidence and indifference. To prevent evils of this nature a prudentist scale of premiums has been adopted by the Telegraph Clerks' Provident Fund, which is considered excessive, and has given rise to no small degree of dissatisfaction amongst the class for whose especial advantage the Fund was established. It has been urged that the conditions to be complied with by intending members are far too exacting, and that the restrictions imposed upon free members would debar them from manly exercise and sports of the field, except at their peril. With respect to the first of these objections, we have reason to believe that in the rules of nearly all respectable institutions, the managing committee reserve to themselves the privilege of demanding proof of age, &c., by the production of necessary certificates, where any doubt exists as to the representations of applicants for admission; and we are assured that in the Telegraph Clerks' Provident Fund no demands for certificates are ever made except in cases of apparent misrepresentation. The other point at issue was very easily explained by Mr. George Sheward, at the annual meeting of the Fund held on the 8th instant. Rule 9 appears to exclude all members from receiving sick pay whose illness is caused by "having been engaged in any games or sports," &c., but when it was shown that the word "unlawful" had, by some unhappy accident, been omitted before the word "games" in the preceding sentence, it at once became apparent that nothing but due caution had been exercised in framing the laws.

In all class or local benefit societies it is necessary to provide against extraordinary risks, for in their establishment we proceed in violation of the laws of average (on which all calculations of premiums should be based) to effect a condition of fraternal union—ignoring general principles, adopting a conservatism, and seeking isolation. A question at once arises—Is it more conducive to the interests of any class to associate for the purpose of mutual protection and advantage, or for each profession, trade, or guild to sink its individuality in the community? Our large general insurance companies, such as the "Royal," can with safety grant policies on far more reasonable terms to the insurer than minor associations; because the magnitude of their transactions will admit of greater speculation, and because there are many sources of revenue tending to counterbalance the great risks they hold (such as lapsed policies, &c.), which do not exist in the special institutions to which we have referred. It therefore appears that the Telegraph Clerks' Provident Fund, by reason of its high rate of subscription, has been founded upon a good basis, with every prospect of being able to meet all demands, present and future, upon its exchequer; and we are led to ask—Why do the telegraph clerks generally manifest so great an indifference to its claims? Is it that as a class they are improvident? Are they regardless of social obligations? We can, from an intimate acquaintance, answer these queries in the negative. Then, why do they not avail themselves of the advantages offered, and unite together in the bonds of brotherhood? Surely there is need of union. We have endeavoured to solve this problem, and will give the result of a few inquiries into what appears to us a matter of great importance, although our remarks would create an unfavourable impression on the mind of a person less disinterested than the one to whom we shall be obliged to refer.

Few men care to make the gentler sex acquainted with their troubles, unless in cases where a closer interest exists than that which arises from the performance of official duty. Men are excessively jealous of their status in society, and, while willing to acknowledge woman as co-equal, they still entertain convictions as to woman's place and power which they seldom care to express. But the truth must be spoken when its suppression is found to impair the usefulness of a good institution; and, while according a just meed of praise for valuable services, and acknowledging the energy, perseverance, and singleness of purpose brought to bear in the establishment of the Telegraph Clerks' Provident Fund, we venture to affirm that were the truly benevolent lady secretary to retire from the position which she has certainly filled with honour to herself and credit to the Fund, and make room for one of the sterner sex, then the accession of members would not only strengthen the society, but give Miss Oppenheim the satisfaction to know that the institution which she had inaugurated had become a blessing to thousands instead of its advantages being limited to a few persons employed by one Company. Another matter has been brought under our notice, to which we shall briefly advert. Englishmen, when ill especially, are very sensitive; and, although the best medical advice may be procurable from foreign lands, and notwithstanding that continental chemists may excel in the laboratory, still Englishmen have always manifested a partiality for the good offices of their own countrymen in times of pain and suffering, and for this reason we are inclined to think that some little indiscretion has been manifested in the appointments of Dr. Sutro and Mr. Baumgatten on the acting medical staff of the Telegraphic Clerks' Provident Fund. We have not a word to urge disparaging the abilities of these gentlemen; on the contrary, we believe that their position in society has been attained by the exercise of talent in their several professions. It is not a question involving the reputation of these gentlemen, so much as the policy of violating national prejudices, which should always receive consideration in cases where the support of a large class is sought for any organisation. We have now spoken out the sentiments of several of our correspondents, being persuaded that those who are now seeking to extend the usefulness of the Telegraph Clerks' Provident Fund are only too anxious to learn the cause of the indifference with which their labours have been hitherto received.

CRINOLINE has been put to a new use in Australia. At Wagga Wagga the telegraph wire broke, and there being no other suitable material at hand for repairing it, a lady kindly lent her crinoline, which, being dissected and used to tie the electric wire together, enabled the operators to use the line.

ELECTRICAL DISCOVERIES.

II.

Dr. Desaguliers commenced his experiments in 1739. He introduced the term *conductor*, to that body to which the excited tube conveys its electricity. He called bodies, in which electricity may be excited by rubbing or heating, *electric per se;* and *non-electric* when they receive electricity, and lose it at once upon the approach of another non-electric. In the year 1742, several Germans engaged in this subject. Mr. Boze, a professor at Wittemberg, revives the use of Hauksbee's globe, instead of using Grey's glass tube, and added to it a *prime conductor.* Mr. Winckler substituted a cushion instead of the hand, which had before been employed to excite the globe. Mr. P. Gordon, a Benedictine monk, and professor of philosophy at Erford, was the first who used a *cylinder* instead of a globe. With his electrical machine he conveyed the fluid through wires 200 ells in length, and killed small birds. Dr. Ludolf, of Berlin, in the year 1744, kindled by electricity the *etherial spirit* of Frobenius, by the excited glass tube; the spark proceeding from an iron conductor. Mr. Boze fired gunpowder by electricity. Mr. Gordon contrived the electrical star. Mr. Winckler contrived a wheel to move by the agency of the same fluid. Mr. Boze conveyed electricity from one man to another by a jet of water, when both were placed upon cakes of resin, six paces apart. Mr. Gordon fired spirits by a jet of water; and the Germans invented the electrical bells. Mr. Gralath fired the smoke of a candle just blown out, and lighted it again; and Ludolf the younger demonstrated that the luminous barometer was made perfectly electrical by the motion of the quicksilver.

Mr. Collinson, in 1745, sent to the Library Company of Philadelphia an account of these experiments, together with a tube, and directions how to use it. Franklin, with some of his friends, immediately engaged in a course of experiments, the results of which are well known. He was enabled to make a number of important discoveries, and to propose theories to account for various phenomena, which have been universally adopted, and which bid fair to endure for ages.

In the year 1745, such was the attention given to the subject of electricity, that experiments upon it were publicly advertised and exhibited for money in Germany and Holland. Dr. Miles, of England, in the same year fired phosphorus by the application of the excited tube itself, without the intervention of a conductor. It was at this period that Dr. Watson's attention was given to this subject. He fired air, made inflammable by a chemical process, and discharged a musket by the electric fluid. He made many experiments, some of which will be described as we proceed.

The year 1745 was made famous by the discovery of the *Leyden Phial* by Mr. Cuneus, a native of Leyden. It appears also to have been discovered by Mr. Von Kleist, dean of the Cathedral in Camin, about the same time. By this discovery, electricity could be accumulated and severe shocks given. Mr. Gralath, in 1746, gave a shock to twenty persons at once, and at a considerable distance from the machine. He constructed the electrical battery by charging several phials at once. Mr. Winckler, and also M. Monnier, in France, transmitted the electric fluid through several feet of water, as a part of the circuit. M. Nollet, in France, killed birds and fishes, by the discharge of the Leyden jars. Improvements were made by Dr. Watson, and others, in the Leyden phial, by coating the inside and the outside of it with tinfoil. Abbe Nollet gave a shock to 180 of the guards, in the king's presence; and at the grand convent of the Carthusians in Paris, the whole community formed a line of 3,600 feet in length, by means of wires between them. The whole company, upon the discharge of the phial, gave a sudden spring at the same instant. The French philosophers tried the same experiment through a circuit of persons, holding wires between them, two and a-half miles in length. In another experiment, the water of the basin in the Tuileries was made a part of the circuit.

M. Monnier the younger, to discover the velocity of electricity, discharged the Leyden phial through an iron wire 4000 feet in length and another 1319 feet, but could not discover the time required for its passage. Dr. Franklin communicated his observations in a series of letters to his friend Collinson, the first of which is dated March 28, 1747. In this he shows the power of points in drawing and throwing off the electrical matter. He also made the grand discovery of a *plus* and *minus*, or of a *positive* and *negative* state of electricity. Shortly after, Franklin, from his principles of plus and minus state, explained, in a satisfactory manner, the phenomena of the Leyden phial. Dr. Watson and others in July 18, 1747, conveyed the electric fluid across the Thames at Westminster Bridge; the width of the river making a part of the circuit. On the 24th of July, he tried the experiment of forcing the electric fluid to make a circuit with the bend of the river, at the New River at Stoke Newington. He supposed that the electric fluid would follow the river alone, through its circuitous windings, and return by the wire. He suspected from the result of this experiment, that the ground also conducted the fluid. On the 28th, he proved the fact by supporting a wire 150 feet in length upon baked sticks, using the ground as half of the circuit. On the 5th of August he tried another experiment of making the *dry* ground a part of the circuit for a mile in extent, and found it to conduct equally as well as water. The last experiment was tried at Shooter's Hill, on the 14th of August, of the same year. But one shower of rain had fallen for the five preceding weeks. The wires, two miles in length, were supported upon baked sticks, and the dry ground was used for the return, two miles of the circuit. They found the transmission of the electric fluid to be instantaneous. Mr. Canton, in England, and Beccaria, in Italy, acquired distinguished reputation for their electrical researches. They both discovered, independently of one another, that air was capable of receiving electricity by communication, and of retaining it when received. Mr. Canton also, towards the latter end of the year 1753, pursued a series of experiments which prove that the appearance of positive and negative electricity which had hitherto been deemed essential and unchangeable properties of different substances—as *e.g.* of glass and sealing wax—depend upon the surface of the electrics and that of the rubber. This hypothesis, verified by numerous and incontestible experiments, occasioned a controversy between Mr. Canton and Mr. Delaval, who still maintained that these different powers depended entirely upon the substances themselves.

The theory of two electric fluids always co-existent and counteracting each other, though not absolutely independent, was maintained by a course of experiments of silk stockings of different colours, communicated to the Royal Society by Mr. Symmer, in the year 1759, which were further pursued by M. Cigna, of Turin, who published an account of them in the Memoirs of the Academy at Turin in 1765.

REID'S PRESSURE TANKS FOR TESTING SUBMARINE CABLES.

The following is a description of Mr. Reid's patent machinery for testing the cores of submarine cables under pressure, referred to in our columns last and the present week. Mr. Reid had, some years ago, employed at different times several modes of testing telegraph wires for submarine purposes, such as immersing them in the sea at different depths, &c.; the plan now described was found to be a great improvement over that employed by the Gutta-Percha Company in having the wires tested in the canal, with seldom more than twelve inches of water over them.

The plan of testing in the sea, however good, has some disadvantages, such as stormy weather, the danger of having the wire injured on board ship, or in the transit to and fro, &c. Mr. Reid has, therefore, devised and adopted the following plan, which, for simplicity for giving a fair and impartial test of wires to any extent required, seems to provide for all contingencies that may arise in making telegraph cables effective:—

The inventor takes a strong iron vessel capable of containing five miles or more of core; it is made air and water-tight, and is filled with a number of air-tight stuffing-boxes for the purpose of passing the ends of the wire out of the cylinder and connecting them with a galvanometer. The vessel is also filled with gun-metal valves at top and bottom for the purpose of exhaustion, and for filling and discharging the water from the cylinder. The vessel weighs, in round numbers, about seven tons. To explain the working fully, the vessel or cylinder is filled from the top with as much wire as it will contain, bringing the ends of the several coils or drums through the stuffing-boxes already described; the cover is then put on the top of the cylinder and bolted down, having a ring of india-rubber for a joint. The air-pump, which is worked by steam power, is then applied, and a vacuum is formed by exhausting all the air contained in the cylinder and that of the core. Hitherto gutta-percha, with but one exception—a length of twenty miles manufactured by Messrs. Wells & Hall for the India Government—has only been

employed, and it is found that in the process of manufacture a considerable quantity of air has been mixed up with it, forming what is called air bubbles, and sometimes to be in places porous and spongy; in all such places the cavities which are filled with air have nearly reached the conductor, and in many cases must in time have proved fatal to the cable. To remedy this defect, the object of the air-pump is to remove all the minute particles of air. When the vacuum is considered perfect, as shown on the vacuum gauge, the exhaustion tube is closed, and the valve opened for the admission of water, which at once fills the cylinder, and occupies the spaces in the gutta-percha formerly occupied by the air. The hydraulic pump is now brought into action, and exerts a pressure equal to 600 or more upon the square inch, and after this pressure has remained for ten or fifteen minutes the indication on the galvanometer is again recorded, and if the needle remains quiescent it may be considered that the cable is safe for a depth of 250 fathoms; the pressure is still continued till it equals a column of water whose height is equal to the depth of the sea where the cable is to be laid, adding a sufficient margin to the pressure to make it perfectly safe, on the same principle as testing a beam or girder that has to carry a given weight, the pressure must exceed this weight or its safety becomes endangered. If we suppose a cable destined for the Atlantic, and the depth to be 2,000 fathoms, equal to 12,000 feet, the pressure applied in this case would be 5,295 lbs. on the square inch, equal to 2 tons 7 cwt. 1 qr. 3 lbs. When this pressure has remained on for fifteen minutes, again note the galvanometer, and if still quiescent the cable is sound, and may be safely immersed to the required depth. When the wire is removed from the cylinder it must be carefully wound off from one drum on another, passing through the hands of a careful operator, who will find a slight indentation on the surface where the pressure has acted on a crevice containing air. A thin, sharp knife must be passed under this indentation, and reach the bottom; if only slight it may be tooled up and restored; if it is a serious flaw it must be cut out, and the cable proceeded with. The further advantage of this process of testing is that the flaws and defects are all discovered at an early stage of the cable's progress, and before the expensive process of sheathing the cable with steel or iron wires has commenced, and the detection becomes more difficult. The engineer has now the satisfaction of knowing that he has a perfect core, and when laid in the ocean's depths it will not be subjected to any more pressure than it has already been subjected to, and that if carefully laid, and free from mechanical injury, the cable will work satisfactorily, and fulfil all the conditions that are anticipated from it. The great and crying evil with all deep-sea telegraphs hitherto made was the careless and hurried manner in which they were manufactured, and without a proper amount of inspection and supervision. The cable constructed for her Majesty's Government, and laid between Malta and Alexandria—the cable laid between Toulon and Algiers for the French Government—the cable which is now being laid for the Indian Government in the Persian Gulf—have all been subjected to pressure in the above tanks; and the proposed new Atlantic cable is, we believe, to be thoroughly tested in a similar manner.

THE INDIAN TELEGRAPH CABLE.

ON the Mekran coast, about 250 miles west of Kurrachee, the peninsula of Ras Noo is joined to the mainland by a narrow sandy isthmus, on which is Gwadur, a wretched town of mat-and-mud-built houses, inhabited chiefly by Beloochees, but subject to the Imaum of Muscat, who is represented by an Arab governor and guard. To the north of Gwadur the soft friable sandstone, the prevailing formation along the coast, increases in height and irregularity, the mountain ridges taking every conceivable form of pinnacle and buttress until they appear like a series of vast ruined castles and cathedrals. To the west extends a circular bay, some nine or ten miles across, with a regular sandy bottom, admirably adapted for receiving a submarine cable, and here commences the first section of the Indian cable, the land line eastward to Kurrachee being already completed and the telegraph-office in full operation, to the great marvel of the natives as well as of the chiefs, who come down to Gwadur with their retainers as far from the interior as the neighbourhood of Herat.

On the evening of the 4th February all the steamers and cable-ships belonging to the section (which had met at the rendezvous some days previously, with a punctuality auguring well for the future success of the expedition), having landed the heavy shore cable, started westward for Mussendom. The Victoria had been previously stationed on the course, some miles out to sea, to mark the first point where the cable might have otherwise run some danger of being laid upon an unsuitable bottom. The Coromandel, with Colonel Stewart, R.E., on board, piloted the course; following her, the Zenobia towed the Kirkham, Sir Charles Bright and his staff laying and testing the cable from her at the rate of about five miles an hour.

At noon on the 5th, 75 miles were laid, and at half-past 10 on the morning of the following day, having finished the 187 miles on board the Kirkham, the squadron came to anchor in lat. 25 19 N., long. 59 9 E., off Ras Mundanny, a spit of low swampy land between Ras Tank and Ras Zegin.

On the afternoon of the 7th, having joined the end to the cable on board the Marian Moore, the ships started again, the Kirkham returning to Bombay in tow of the Semiramis. At 9.30 a.m. on the 8th the ships anchored off Ras Jask, at the entrance to the Gulf, 298 miles being laid, and waited until the evening, so as to make the Arabian coast on the following morning.

Shortly after midday on the 9th, 357 miles having been laid, the Marian Moore anchored near the landing-place at Malcolm's Inlet, a sandy inlet ten miles in length, surrounded by steep and sterile mountains, and about 15 miles from Cape Mussendom, which gives its name indefinitely to the adjacent land.

The shore end was landed on the 13th, the interim being occupied in erecting a short length of land line and fitting up tents and accommodation for the operators. On the 14th the Marian Moore, with Messrs. Laws, Webb, Alexander, Lambert, and other engineers and electricians assisting in the work, started for Bombay, in tow of the Zenobia, to prepare and bring up the Tweed and Assaye, which arrived there with an aggregate of 730 miles of the cable on the 6th and 13th of February respectively. So far nothing could have been more successful, the cable when laid being in very far higher electrical condition than any other line yet submerged, and having been laid without the smallest drawback or embarrassment, either mechanical or electrical.

If the other arrangements proceed with equal regularity, we may shortly look for the completion of the Anglo-Indian Telegraph, though it is probable that some little time may intervene between the completion of the cable in the Persian Gulf and the establishment of the land lines in Mesopotamia and Persia on such a footing as to admit of the lines being opened to the public for the regular carriage of messages.—*Times.*

ON MAGNETIC STORMS AND EARTH-CURRENTS.

By CHARLES V. WALKER, Esq., F.R.S., F.R.A.S.

I.

AN account of the extensive and interesting investigations and observations conducted by Mr. Walker, have been from time to time presented to the Royal Society, and are printed in its transactions. The information contained in these papers is exceedingly valuable, and will, we believe, be read advantageously by those engaged in telegraphic operations. The reports contain numerous tables and diagrams in illustration of the phenomena which at times have had considerable influence upon the working of the telegraphic lines of this and other countries.

The author first refers to the movements of telegraph needles, due to causes external to the apparatus itself, which were noticed very soon after the first electric telegraphs were erected. In illustration, he gives some extracts from his diary at various dates in the year 1847; and a copy of a General Order which he issued on the 25th of October in that year, calling upon the telegraph clerks under his charge in the south-eastern districts of England to take notes of these phenomena, and forward them to his office. The telegraph in use there then, as well as now, is Cooke and Wheatstone's needle instrument, having one or two vertical galvanometers.

He makes some extracts from his "Electric Telegraph Manipulation," published in 1850, showing that the impression expressed in the extracts from his diary, of a connection between auroral manifestations and the phenomena in question, was confirmed. And he refers back to the published account of "The daily Observations of Magnetometers at the Royal Observatory, Green-

wich, in the year 1847, and extracts from it the reports made of the behaviour of the magnetometers on the days cited, showing that they were very much disturbed.

The author describes the time in question as a period of great disturbance; so much so, that in the year 1848 he was constrained to adopt a device by means of which the telegraph communication might be carried on, notwithstanding the presence of these foreign influences in the wires. But his plans were hardly matured and in operation before the cause disappeared; the disturbances almost entirely ceased. The years 1847 and 1848 had been periods of great activity. The year 1849 was a period almost of inaction; and this continued, a circumstance which, although it caused at the time some surprise, tended to withdraw attention from the question.

A paper by Mr. W. H. Barlow is then referred to, which was read before the Royal Society on May 25, 1848, and subsequently published in the "Philosophical Transactions," and in which a very interesting set of observations are given, made at Derby in May, 1848, upon various lines of telegraph centreing in that city. The relative bearing of the terminal stations, and not the route of the wires, is at the basis of these observations; and it is considered that the wires conveyed a portion of a terrestrial current of electricity, which current appeared to travel between S. 28° W. and S. 75° W.

The author goes on to state that, after a comparatively long lull, with only here and there a sign of moderate activity, attention was again called to these earth-currents about the year 1856; and more definite instructions were issued for observations to be made, and returns sent in, which has led to a large accumulation of observations, commencing early in 1857. It is not his purpose to discuss the mass of observations, nor to extract from them the dates of great disturbance; for this would only go to show the general relation between earth-current, magnetic disturbance, and aurora, which is already well established.

The most notable period of disturbance that has occurred since electric telegraphs have been in existence, was from August 27th to September 6th, 1859. It was recognised in one or more of its modes of manifestation, not only in Europe and America, but in Australia. Notices of the phenomena, collected in all parts of the world, are given by Prof. Elias Loomis in the "American Journal of Science and Arts," and occupy ninety-three pages. Two articles in "Les Archives des Sciences Physiques," by Prof. De la Rive, are also referred to. Referring to the reports in question, it was evident to the author that those who, like himself, had electric telegraphs under their control, had, to a certain extent, failed in their duty. He had, it is true, collected many observations, but they had been neither discussed nor published; and M. De la Rive had to express his regret that the returns which reached him of this great storm gave him no clue as to the direction of the currents; and for lack of this information the conclusions to which he arrived admit of reconsideration. Mr. Walker, upon learning this, took the matter up more actively. The south-eastern district, where the observations were made, may be regarded as bounded N. by the Thames, E. and S. by the British Channel, and W. by the other southern counties of England. Kent, Surrey, Sussex, and Berkshire, are concerned in contributing to the observations. Eighteen pairs of terminal stations have been selected; the eighteen direct lines, drawn to connect each pair of stations, make different angles with the magnetic meridian. The view taken by the author is that a flood or stream of electricity, of indefinite width, is drifting across the country, and that portions of it appear as derived currents in the telegraph wires, entering by the earth connection at one terminus, and leaving by like means at the other. The derived current enters at the terminus nearest to the point of the horizon *from* which the main current flows, and leaves at that nearest the point *toward* which it flows.

A Table is then given of the eighteen pairs of stations, their names, the angle their joining line makes with the magnetic meridian, the direct distance from station to station, and the distance by the wire route.

The returns made of the August-September storm of 1859 are more meagre than usual, for reasons that are given; and the author explains, that on the very days when the clerks would be most valuable as observers, they are more occupied in their ordinary duties from the presence of the disturbances, which harass them in their work; and on this account he expresses himself the more indebted to those who have observed so well at such times, especially to Messrs. J. Dyke, D. Malpas, and T. Pulley.

An extract is next given from the last Report of the Astronomer-Royal to the Board of Visitors, stating that he cannot extract from the returns made by telegraph clerks an idea of the phases of earth-currents, to make them comparable with those of magnetic storms. Into these views Mr. Walker enters; and while pleading guilty to not having contributed from his district any observations to the Royal Observatory, he explains that it is because he had not heretofore had the opportunity of subjecting what he had collected to anything like a fair discussion. But he quite agrees with the Astronomer-Royal, in thinking that it may turn out to be desirable that observations of earth-currents should be made in a magnetic observatory, side by side with those of the magnetometers, on wires specially erected, which wires, as appears from the sequel, need not be of any great length; for the Margate-Ramsgate group, three miles in length, is found to be very active, and action has been found on a length of 972 yards.

Reports are then given of the behaviour of the needles during the August-September storm of 1859, followed by a Table containing a series of consecutive observations which the Ramsgate clerk made from August 29th to September 2nd, and which show the duration and changes of the currents, the *general* direction in which they were moving, and their comparative values; details which were wanting to M. de la Rive when he wrote on this storm.

The author adverts to the remarkable manner in which the change from a current in one direction to a current in another is brought about, by no drift of anything like a "circular storm," nor by any kind of axial rotation; and in contrast to the calm minutes in the midst of an active period, he cites cases of activity, which are common enough in periods otherwise calm. He shows also how the value of the derived current varies with the size of the wire.

Passing from this more general view, he describes the arrangement made for forming a more definite opinion of the value of the currents collected, and how he proposed to turn to better account the next storm-days, of which some good cases followed on August 8 to 12 inclusive, and on Sept. 7, 1860, which is the last storm-day that has occurred. On the days in question a good series of observations were made, the results of which are given in Tables which accompany the communication. These Tables are discussed, and the values of the currents of either kind are given in detail in degrees and in time; and the means are deduced. Before discussing the results, the author takes occasion to call attention to the very active habit of the Margate-Ramsgate line, and to the high value of the currents collected there, although, as before stated, its length is only three miles.

On discussing the Tables, it appears that 1 current in 20 had a duration of less than half a minute. The proportion of currents above and below 5 minutes duration was 1 to 2·32. Of those above 20 minutes and those between 5 minutes and 20 minutes, the proportion was as 1 to 3·6. The 1-minute currents are most in number; then, in order, the 2-min., 3-min., 4-min., ½-min., and 5-min. The observations, which embraced a period of 50 hours 42 minutes, show very nearly an equal duration of N. and S. currents, the difference being 21½ minutes in favour of the S. currents. The mean duration of N. currents was 9·51 min.; of S., 9·42 min. The proportion of currents exceeding 45° in value to those below 45°, was as 1 to 6·49. The 15° to 20° currents are most in number; then follow, in order, the 5° to 10°; then the 10° to 15°. The mean value of the N. currents was 28°·01; of the S., 26°·07.

Mr. Walker then refers to the opinion of M. De la Rive, that the S. currents are merely due to the secondary polarities acquired by the earth-plates, and shows that it is not in accordance with the facts here accumulated, for, from the results given, it would be hard to say that either the N. or the S. currents exceed the other in value; and no one thing could here be said of the N. currents, which might not with equal truth and equal force, be said of the S. currents.

The remarks thus far have reference to a solitary telegraph group, from which the *general* drift, but not the *special* direction of the earth-currents, is gathered. The action produced might be equally due to a current running in a direction many degrees to the right or many degrees to the left of the direct line joining the two stations. In illustration of this, a series of diagrams have been prepared, in the first of which the lines of direction (referred to the magnetic meridian) of all the telegraph groups are set off; in others, the lines alone on which observations were made at a given time, are laid down. In proportion as the two boundary lines in any case make a greater angle with each other, the absolute

direction of the current is more nearly determined. Cases are given and discussed, and the conclusions progressively arrived at, in order, as lines with a greater angle occur, to give the dimensions and position of the arc of the horizon within which the resultant line is situated. When observations are obtained from only one line, the resultant is known to be somewhere in one half of the horizon; but the place is not proximately defined. Frequent observations were made on a pair of lines making an angle with each other of 74°. This reduced the limit, within which the resultant was to be sought, to 106°. Other observations were made on a pair of lines making an angle of 138°, which reduced the limit to 42°. And finally, a table of observations is given, which were made upon a pair of lines making an angle of 149°, which reduces the arc within which the resultant is to be sought, to 31°; and this is the closest result that has yet come out from absolute observation. This arc is within the limits of each of the larger arcs that come out from the previous observations, and it extends from 46° to 77° E. of the magnetic north.

The currents in all the cases cited were not confined to the limiting lines, but were constantly found in one or more of the intermediate lines, and always in a direction consistent with the view taken. In the last case, where the arc is reduced to 31°, and in most of the observations tabulated, the current in the limiting lines was so strong that the author felt himself fully justified in concluding that if he had lines of telegraph beyond these limiting lines, he should have found currents: he has assumed 10° as not likely to be beyond the range; and this reduces the arc to 11°; and knowing from experience in which limiting line the current is apt to be more active, he has divided the arc of 11° into the proportion of 7° to 4°, and has set off a line, which may be taken to be a very close approximation to the direction in which the currents move. It falls 63° E. of magnetic N.; and by deducting from this 21½°, the value taken for magnetic declination, the direction of the earth-currents, referred to the astronomical meridian, is 41½° E. of N., or N.E. within 3½°. When the currents change in direction, it becomes S.W. within 3½°. The cases discussed go back as far as 1857; and there appears to have been the same general direction during that period. A N.W. and S.E. direction for the resultant is not known.

The author discusses, as well as he can from the few data before him, a few observations made in France and Switzerland. They are meagre in detail, but confirm the impression, which would naturally arise, that some such general direction will be found there. He also refers back to Mr. Barlow's paper, in which an arc of 47° was obtained, and within which the N.E. bearing was situated, being 30° from one limit of the arc, and 17° from the other; showing that from the year 1848, to the present time, no great change in azimuth has taken place.

A few remarks follow in explanation of certain specialities and anomalies in the behaviour of some of the lines in respect to their azimuths, and on the relative conductive power of the various geological strata concerned. And the author thinks it very probable that many of the currents observed some thirty years ago in the metalliferous veins in Cornwall, may have been veritable earth-currents, and may have been coincident with magnetic storms.

Having determined the proximate direction of earth currents, Mr. Walker referred to the magnetometers of an observatory merely as magnets, in order to discover whether the magnetic disturbances at a given time were in accordance with the known reaction of electric currents and magnets. The Astronomer-Royal, as well as General Sabine, furnished him with the photograms from Greenwich and Kew respectively, which he required for making the comparisons. He has selected some cases of earth-currents, and has set them out in curves, side by side with the Greenwich or Kew curves, and has found a sufficient amount of coincidence to confirm the conclusion that arises, and to encourage further enquiries. He has laid down the position which the declinometer and the horizontal-force magnetometer would tend merely as magnets to assume under the influence of currents moving in the assigned direction, and has given some extracts from the Greenwich observations in support of the views he takes.

The author has made no attempt to trace the origin of the currents in question. He simply takes them as he finds them, and endeavours to arrange them in some degree of order; and he touches very lightly upon terrestrial magnetism itself. He considers that, "although we are considerably in the dark as to the forms of force in operation to make up the *whole* of the causes concerned in magnetic disturbance, we are yet quite certain that the current form of force is at least in *part* concerned." And he adds, "We can collect this force and measure it, and deal with it independently. We can receive the results and record them photographically, as foreshadowed by the Astronomer-Royal, side by side with those of the magnetometers. And doubtless, should such combined results come at any future day under discussion, and more so, should they pass into the hands of General Sabine, a method would be devised of eliminating the value due to these known causes, that is, due to earth-currents absolutely collected, and thereby rendering the value thus corrected more manageable; and we might get one step nearer towards penetrating into the more recondite causes of the earth's magnetism and its variations." And this cannot be accomplished until Mr. Airy's suggestion, of including the earth-currents in the observations of a magnetic observatory, is realised.

MISCELLANEOUS EXPERIMENTS.

ON charging a portion of gutta percha covered copper wire, and then putting it to earth, found that, after a short period, a second or residuary charge remained in the wire. After more careful experiments, this residuary charge was found to manifest itself ten or twelve times—its amount being greater when some time was allowed to elapse after the previous contact with the earth. Concluded from this that the residuary resides in the inequalities of the gutta percha, and creeps gradually to the copper, where it is accumulated, if sufficient time be allowed for the purpose. Going further, it may be presumed that gutta percha is porous to a certain extent; and the residuary resides in those pores—or, in other words, in the structure of the material. [Such is the case with all other insulating materials.—ED. T. J.]

Eight miles were next charged negatively and eight miles positively (seventy-two cells). On connecting the respective eight miles together, produced neutrality. Then took off one mile from *one* group of eight, then connected the eight to the seven, and found a residuary charge of 8°; then took off another mile, and connected eight with six, and found a residuary of 16° 30′; then took off a third mile and so on, and obtained 24°, 32° 30′, 40°, 48° 30′, 59°, and 68°.

Experiments with a Peltier Electrometer.

One pole of sulphate battery, connected with the stem of instrument, the other pole being attached to earth-plate in successive increases of series, as under—with twelve cells, the deflection was 0°; twenty-four cells, 2° 30′; thirty-six cells, 5°; forty-eight cells, 7° 30′; sixty cells, 10° 30′; seventy-two cells, 12° 30′; 144 cells, 26° 30′.

Continued charge on Insulated Wires.

The charge was kept on for some weeks, but no change whatever took place in the insulating properties of the various materials, which consisted of pieces, five feet each in length, of the following dimensions, immersed in water:—1st. copper, 8·32 in diameter; gutta percha, 6·32 in thickness; 2nd. copper, 4·32 in diameter; gutta percha, 6·32 of an inch in thickness; 3rd. copper, 2·32 in diameter; gutta percha, 6·32 in thickness; 4th. copper, 2·32 in diameter; gutta percha, 3·32 in thickness; 5th. copper, 2·32 in diameter; gutta percha, 12·32 in thickness; 6th. copper, 1·32 in diameter; gutta percha, 1·32 in thickness; 7th. copper, 2·32 in diameter; gutta percha, 2·32 in thickness; 8th. copper, 2·32 in diameter; Ratcliffe's gutta percha, 6·32 in thickness; 9th. copper, 2·32 in diameter; Wray's compound, 6·32 in thickness; 10th. copper, 2·32 in diameter; Daft's vulcanized india rubber, 3·32 in thickness; 11th. Copper, 2·32 in diameter; Wells & Hall's india rubber, 2·32 in diameter, 2·32 in thickness; 12th. copper, 2·32 in diameter; Silver and Co.'s india rubber, 3·32 in thickness. The number of elements employed, 512. Muirhead's improved sulphate battery.

THE galvanic fluid affects all the senses. Nothing can be more disagreeable than the shock, which may even be fatal if the battery be very powerful. A bright flash of light is perceived with the eyes shut, when one of the wires touches the face and the other the hand. By touching the ear with one wire, and holding the other, strange noises are heard, and an acid taste is perceived when the positive wire is applied to the tip of the tongue, and the negative wire touches some other part of it. By reversing the poles, the taste becomes alkaline. It renders the pale light of the glow-worm more intense. Dead animals are roused by it as if they started again into life; and it may ultimately prove to be the cause of muscular action in the living.

THE INTERNATIONAL EXHIBITION, 1862.

(*Continued from page* 140.)

Digney Brothers, Paris, M. (France, 1,414), exhibit an automatic transmitter adapted to the usual Morse signals.

Messrs. Digney punch in a strip of paper long or short rectangular holes, corresponding to the dots and dashes required. The long and short holes are made with separate punches, placed side by side; thus all the dots are in one row, and all the dashes in another beside it. These punches are depressed by separate levers, which are so connected with pauls that the depression and rise of the dot lever moves a ratchet-wheel, connected with a drawing-roller, two teeth forward, whereas the dash lever moves the same wheel three teeth, and a space lever, which has no punch, moves the wheel one tooth forward. The paper is thus drawn forward one, two, or three times the length of the dot punch, according to the lever depressed.

When the paper has been thus prepared, it is placed in the transmitting apparatus, through which it is drawn by clockwork. In its passage it passes over a roller with two grooves, corresponding to the centres of the two lines of holes.

Two little bent rocking levers have pins on their ends which rest in these grooves when not covered by the paper. The other ends of the two rocking levers are used to make contact with two metal stops, against which they are pressed by light springs. The stops are both in connection with one pole of the battery, the other pole of which is in connection with the earth. The rocking levers are both in connection with the line. When plain paper is passing over the roller, the pins of both levers are lifted by the paper out of the grooves, and the other, or contact ends, are held back from the stops. The circuit is therefore interrupted; when a hole passes under either pin it falls through into the groove, and the other end of the lever comes in contact with the stop, completes the circuit, and sends a current through the line. The duration of this current obviously depends on the length of the hole and the speed at which the paper is drawn through. Messrs. Digney by this plan avoid the difficulty of making good contacts through the holes in the paper. These holes play a purely mechanical part, the contacts are made by dead pressure, and the play of the levers is considerably greater than the thickness of the paper.

So far this arrangement is a real improvement on some of the plans hitherto proposed. It has, however, various defects. The punches are very large, they require considerable power to work them, and would be far more fatiguing to the hand than the usual Morse key, or the little punching machine of Professor Wheatstone's arrangement. The feed or drawing motion for the paper in the punching instrument is bad, and gives very irregular spaces, as must be the case wherever drawing rollers are used. The paper always slips a little, and slips very unequally. A great deal of paper would also be used by this transmitter. The advantage claimed for it—that the common Morse alphabet can be retained—has little weight, since Professor Wheatstone's arrangement, free from all the defects just named, can with perfect ease be made to send the common dots and dashes instead of positive and negative dots. Finally, this key is said to transmit only about twenty-five words per minute, or not more than a good clerk will send by hand.

Siemens & Halske, Berlin, M. (Prussia, 1,413), exhibit an automatic magneto-electric transmitter, working by means of movable metal types, and intended for use with the usual Morse code and the polarized receiver.

Reverse currents are continually induced by the continuous revolution of coils, arranged between magnets as in the other magneto-electric instruments shown by this firm, and driven by a belt from a treadle. The admission of these currents into the line is determined by the type-stick or rod, in which the message has been previously set up in types. These types consist in alternate ridges and hollows, which, however, by no means correspond—in outward appearance at least—to the lines and intervals which are received at the other end of the line, as will presently be explained.

A little bent rocking lever rests with one end on the type, and when lifted up by a ridge makes a contact at its other end, which allows the induced currents to pass into the line, but which falls back and interrupts these currents whenever the ridge ceases. Thus one continuous ridge would allow a continual succession of equal reversals to enter the line, and would produce equally spaced dots on the Morse receiver. If a vacant space or hollow occurred in the ridge, it might produce a continuous line or a continuous space, according to whether the ridge ended just after a positive current had been sent, or after a negative current had been sent, and produced its effect on the polarized receiver. Thus it appears, that not only the *length* of the ridges and spaces forming the type, but the exact *position* of these ridges when passing under the contact lever, relatively to the position of the induction coils in their revolution is of the utmost importance, and that the very same type might send different signals, if differently placed, relatively to what may be called the angular position of those coils.

Messrs. Siemens move the type slide along under the contact lever by an endless screw in connection with the coils, and working into a rack on the type-stick. By that arrangement the rod or stick, which holds the type, always occupies a definite position relatively to the angular position of the coils—*i.e.*, when the induced currents are, say *nil*, there will always be one of a series of definite equally spaced points on the rod, beneath the end of the rocking lever. The next point to observe is that the types themselves always occupy a definite position in the stick. They are held by little projections on the types fitting into transverse grooves in the rods; each type is therefore independent of its neighbours, and so, whatever be the order of its ridges and spaces, they will always make and break contact at exactly the same points of revolution of the induction coil, independently of the position of the type relatively to other types. Each letter has a separate type. When a dot is required, a ridge is placed so as to admit one, say positive current, followed by one negative current, into the line; a ridge of twice the length gives two dots, and a ridge of three times the length three dots. A line will, on the contrary, be produced by a ridge of half the length of the dot ridge, admitting a positive current, but not the succeeding negative one. At the end of the line another short ridge must be placed, so as to admit one negative current to bring back the armature of the polarized receiver.

Wherever a space is required between words or letters, the ridge preceding must end immediately after admitting a negative current. No hollow is required on the type to separate successive dots and dashes; thus a single long ridge gives the letter S, or three dots; a short ridge, followed at intervals by two ridges of double the length, and then one short ridge, gives the letter O, or three dashes. The type admits first a positive current, but stops the negative; after a time it admits by the second ridge a negative current, followed at once by a positive current and an interruption. The third ridge plays the same part as the second; and lastly, the fourth short ridge admits a negative current, followed by an interruption. (It will be clearly perceived that exactly similar effects would be produced if everywhere in the foregoing description positive were written for negative, and *vice versâ*.)

This plan has many good points. The contacts are dead pressure contacts, and can be made with any required force, and consequently with any required rapidity, since every part is strongly made, and metal alone is dealt with. The magneto-electric currents are all of equal and very great intensity, being produced by a continuous motion, which is in this case attended with exactly the same benefit as in Professor Wheatstone's dial instruments, to be presently described. The type-sticks are easily filled in, and hooked one on to the other, so as to follow in unbroken succession for a message of any length. Lastly, the common Morse code is retained. The receiver used in connection with this instrument is a direct ink receiver, with the writing disc revolving in an ink trough, and has been already described.

Messrs. Siemens state that by this instrument they have transmitted messages at the rate of 80 words (or about 400 letters) per minute, through a circuit beginning in London, passing to Paris and back, then to Cromer and back, and finally through a long series of resistance coils. The total resistance of the circuit was equal to 2,550 miles of land line, and was composed of 800 miles of land wire, 50 miles of submarine cable, and 1,700 miles in the resistance coils.

It seems, however, probable that this experiment was inconclusive, as only one earth-plate is said to have been used at the station from which the signals were sent, and to which they returned. It is not certain that the currents ever passed in a legible condition through Cromer or Paris. It is well known that signals can apparently be sent even without a closed circuit, by connecting the battery and receiving instrument between two insulated wires long enough to act as Leyden jars of large capacity. The use of a single earth-plate will not entirely prevent this phenomenon when the earth connection has, as is always the case, a sensible resistance. The surprising number of words sent would entail a transmission at the rate of more than 2,400 reversals per minute, and it is most desirable that their apparently distinct reception should be proved

by further experiment, by which all uncertainty might be removed. M. Guillemin's experiments especially lead the writer to doubt the real transmission of 80 words per minute through the above immense circuit.

Whatever be the effect of the retardation, as proved by further experiment, it must be allowed that Messrs. Siemens' instrument possesses great merit to give the above speed, even through resistance coils.

T. Allan, M. (United Kingdom, 2,850), exhibits a series of instruments (of which his sparkless relay, already described, forms one) intended for the rapid and automatic transmission of messages. Mr. Allan prepares his messages on paper by a punching instrument, and then draws one end of the prepared strip between the rollers of his transmitter, which hereupon starts, and continues, without further intervention on the part of the clerk, to draw on the paper, and transmit the required sequence of currents along the line to the receiving relay and printing instrument, which at once starts, and continues to work without any intervention on the part of the clerk. The sending and receiving instruments are driven by electromotors with local batteries until a short time after the message comes to an end, when they stop, ready to recommence their functions, when the transmitter is started by the introduction of a fresh strip of paper.

Mr. Allan, like many others, uses paper punched mechanically to represent his message at the transmitting end; his alphabet, already described, is composed entirely of groups of dots, and by the depression of a single key for each letter, he punches at one blow the required group. These groups of holes are used in the transmitting instrument to determine the motion or rest of a toothed wheel which gears into these holes. On the axis of this wheel is another wheel acting as a contact maker for a local battery, which works a reciprocating electro-motive arrangement, winding up a barrel spring which drives the mechanism by a train of wheels. Moreover, each beat of the electromotor corresponding to each hole in the paper, sends a single current from a separate battery into the line. Alternately positive and negative currents are sent, one for each dot.

These reverse currents are received by the sparkless relay, and the two local circuits described in connection with that instrument work an electromotor similar to that of the transmitter, besides moving the style which prints the dot. This second electromotor winds up a barrel spring used by a train of wheels to drive the rollers drawing on the paper on which the received message is printed.

An ingenious contrivance (a loose tooth on a ratchet-wheel) is in each case employed to prevent these barrel springs from being overwound, or wound so far as to stop the electromotors. The cessation of the message both at the sending and receiving end allows the barrel spring to run down, owing to the stoppage of the electromotor, and finally breaks the local circuit so as to prevent needless consumption in the batteries. The transmitter is furnished with a key, by which the clerk can send signals by hand in the usual manner, if necessary. Great ingenuity is apparent in every part of these instruments, which can hardly be adequately described without the use of drawings. This system has a better title to the name "automatic" than any of the others, for the functions of the clerk are reduced to the first introduction of the prepared message into the instrument. There are no handles to turn, or treadles to work, or springs to wind up. It is doubtful whether the advantages to be derived from this automatic action are not more than counterbalanced by evils arising from the unavoidable complication. Mr. Allan, however, considers his apparatus less complicated than the usual Morse instruments.

(*To be continued.*)

Mr. Prescott, in his *History of the Electric Telegraph*, gives the following as the rapidity of transmission on the several instruments in use in 1860:—Cooke and Wheatstone's needle telegraph of Great Britain, 900 words per hour; Froment's dial telegraph of France, 1,200; Bréquet's dial telegraph, also French, 1,000; Siemens' dial telegraph, formerly used on the Prussian lines, 900; Bain's chemical, in use between London and Manchester, and formerly, to a considerable extent, in the United States, 1,500; the Morse telegraph, in use all over the world, 1,500; the House printing, used in the United States, to a limited extent, and in Cuba, 2,800; Hughes', and the combination instruments, 2,000. The last three systems are American inventions. Thus it will be seen that to our country is due the credit of inventing the most rapid and the most universally used telegraphic system.

RAILWAY SIGNALLING APPARATUS.

Mr. H. Allan sends us a description of a railway train signalling apparatus, which consists of a black board with a white and red flag painted on the surface on either side, such signals being understood by every one connected with a line of railway.

The pointer or flag staff consists of a very slim slip of ivory attached at right angles to the centre of a light permanent magnet, pivoted and oscillating between the poles of two electro-magnets, so that by changing the circuit, by depressing either key, the permanent magnet is attracted and repelled at the same moment, thus throwing over the pointer, which is retained in this position until the key reversing the circuit be touched. On the back of the dial, as a communicator, is placed a galvanometer, with a weighted needle suspended, oscillating between two bells or glasses, and which forms part of the circuit with the electric magnets, communication being made by a certain number of blows being given to either, by the key being depressed according to the signal blocked.

MR. WM. LADD'S NEW ELECTRO-MOTIVE ENGINE.

This exceedingly ingenious machine consists of four bar electro-magnets firmly secured to the corners of a stout iron plate, forming the base of the instrument. To the top of these is secured a circular brass plate, carrying the break, revolving armature, &c. The connections are so arranged with the break, that the magnetism is excited at the opposite corner alternately.

The armature is formed of eliptical plates of soft iron, from which peculiar form during each quarter of a revolution it approaches two of the electro-magnets. The instant the major axis is in a line with the magnet, the current is changed to the other two, and this is repeated four times in each revolution.

By means of a screw and wheel the power is communicated to a shaft. The whole machine occupies a space of six inches square by seven inches high, and when worked with a small battery it exerts a very considerable power.

CORRESPONDENCE.

FAULTS IN INSULATION.

To the Editor of the Telegraphic Journal.

Sir,—"K. H.'s" opinion is, I think, quite correct. It has always been practically found that the signals received at the station nearest a fault are the strongest, with the batteries and instruments used in this country. In my Handbook I have gone very fully into the "effects of faults in insulation," and have endeavoured to show the reason of the fact "K. H." inquirds about. See pp. 65 to 74.—Yours, &c.,

R. S. Culley.

TELEGRAPHIC FAC-SIMILES.

To the Editor of the Telegraphic Journal.

Sir,—In your journal of the 12th instant you give an account of experiments made in April, 1848, between London and Brighton, with Bakewell's copying telegraph. The inaccuracy of some of the statements being so palpable, I think it right to call your attention to them:—

1st. It is stated that the experiments were made in 1848. That could not be, as at the period in question no telegraph existed between London and Brighton.

2nd. Your correspondent states the rate of speed was about 150 letters per minute. I cannot understand how such a calculation could be made, when it took two whole days before a perfect message was received, and that one occupied nearly one hour in transmission, containing only a few words.

3rd. Your correspondent would lead the public to infer that the messages could be received either visible or invisible, at the option of the operator. Such was not the case, as the "chemical process" was at that time a part of the arrangement to render the message at all visible.

4th. The experiments stated by your correspondent to have taken place in 1848 were first attempted in April, 1851—just three years after the time stated by him.

As it is not fair that the public should be misled by such statements as your correspondent puts forward, I feel it my duty to call your attention to the above, and am,

One who took Part in the Experiments.

ORIGIN OF THE ELECTRIC TELEGRAPH.

To the Editor of the Telegraphic Journal.

Sir,—A few years ago the appended interesting inquiry appeared in a valuable and instructive weekly publication called *Notes and Queries*. I should feel greatly obliged if some of your readers north of the Tweed could furnish me, through the medium of your columns, with some particulars, or, it would be more satisfactory, with a copy of the important letter of "C. M." It is not with a view in any way to detract from the well-deserved credit accorded to Messrs. Cooke and Wheatstone, as the gentlemen to whose joint labours we are indebted for the practical realization of the electric telegraph, that I make the inquiry, but simply to ascertain as far as possible to whom we are indebted for first suggesting electricity as a means of communicating between distant parts.—Yours very truly,

Electrician.

"The Electric Telegraph.

"Powerful as this extraordinary agent has become, and incalculably useful as its operation is now found to be, it would appear that the principle of the electric telegraph and its *modus operandi*, almost identically as at present, were known and described upwards of a century ago. On the occasion of a late visit to Robert Baird, Esq., of Auchmeddan, at his residence, Cadder House, near Glasgow, my attention was called by that gentleman to a letter initiated 'C. M.,' dated Renfrew, Feb. 15, 1653, and published that year in the *Scots' Magazine*, vol. xv., p. 73, where the writer not only suggests electricity as a medium for conveying messages and signals, but details with singular minuteness the method of opening and maintaining lingual communication between remote points, a method which, with only few improvements, has now been so eminently successful. It is usual to attribute this wonderful discovery to the united labours of Mr. W. F. Cooke and Professor Wheatstone; but has any one acknowledged the contribution of 'C. M.,' and can any of the learned correspondents of *Notes and Queries* inform me who he was?

"Glasgow. "Inquirendo."

TELEGRAPHING WITHOUT A METALLIC CONDUCTOR.

To the Editor of the Telegraphic Journal.

Sir,—The following extract is given by a writer in the *Guardian* vol. 2, published in the year 1713, in describing Strada's narrative of an entertainment given before Pope Leo the Tenth and an audience of the greatest eminence, refers to the subject of a poem delivered by one of the great critics, which may doubtless interest your readers, as it shows that telegraphing without a metallic conductor is no new invention, as it must have been known in those days. The insertion in your next publication will oblige,

William U. Corton.

Magnetic Office, Southport, March 21, 1864.

[Extract.]

"Strada, in the person of Lucretius, gives an account of a chimerical correspondence between two friends, by the help of a certain load-stone, which had such a virtue in it, that if it touched two several needles, when one of the needles so touched began to move, the other, though at never so great a distance, moved at the same time and in the same manner. He tells us that two friends, being each of them possessed of one of these needles, made a kind of dial-plate, inscribing it with the four-and-twenty letters, in the same manner as the hours of the day are marked upon the ordinary dial-plate. Upon their separating from one another into distant countries, they agreed to withdraw themselves, punctually, into their closets, at a certain hour of the day, and to converse with one another by means of this their invention. Accordingly, when they were some hundred miles asunder, each of them shut himself up in his closet at the time appointed, and immediately cast his eye upon the dial-plate. If he had a mind to write anything to his friend, he directed his needle to every letter that formed the words which he had occasion for, making a little pause at the end of every word and sentence, to avoid confusion. The friend, in the meanwhile, saw his own sympathetic needle moving of itself to every letter which that of his correspondent pointed at. By this means, they talked together across the whole continent, and conveyed their thoughts across the whole continent, and conveyed their thoughts to one another, in an instant, over cities, mountains, seas, or deserts."

TELEGRAPHIC FEATS.

To the Editor of the Telegraphic Journal.

Sir,—I should not have trespassed on your valuable space again but for the request contained in last week's journal.

A correspondent asks how a sender can be arrested in the middle of a message, or any conversation. I answer, for this reason, after each signal the manipulator or handle in connection with the line is returned to the instrument direct, consequently any signals from the opposite end show themselves immediately, in precisely the same manner as with the bells.

I was fully aware that the Electric Company do not use the ordinary Morse handle, doubtless they have good reasons for adopting Varley's system; the instrument I referred to is the most perfect of its kind, Digney's direct worker.

The advantage of the scrutiniser over the repeater is, that while the sending clerk can go on with his message, the receiver can pay extra attention to any doubtful word, and without much exertion still be in time at the finish to proceed with the next message without causing any stoppage whatever.

I am sorry prejudice has entered the discussion; the only interest I have in the matter is to endeavour, as far as the experience of sixteen years leads me, to further the claims of the instrument that appears in every respect the best for the public service.

I happen to be perfectly acquainted with the bells, not as a clerk, certainly, but have given considerable attention to the construction and capabilities of most if not all instruments in use at the present day.

Reference to my first letter will show that I gave 80 words per minute as the uniform speed.

The term "yarn" was perfectly understood. The mistake was made by "W. H. N.," who said the yarn could not be interrupted, if necessary so to do.

I did not appeal to visitors to judge of the comparative speed. I said *conversation*, which "W. H. N." averred was impossible. I asked *when* the maximum of 50 words per minute was attained?—not, why it was not always.

No inconsistency has been committed on my part respecting the bells. I have given them due credit, only endeavouring to prove the Morse was not inferior. The rule for pausing at intervals does not refer to the ordinary Morse, but to the system used by the Electric Company. I may add, that the speed mentioned by "W. H. N." as despicable to the bells is equally so to the Morse; the great amount of play on the manipulators used by the Electric Company may account for this low rate.

Thanking you for the courtesy displayed in publishing these letters,

I am, Sir, your obedient servant,

Old Double Needle and Morse Clerk.

Dover, March 17th, 1864.

TELEGRAPH CLERKS' PROVIDENT FUND.

To the Editor of the Telegraphic Journal.

Sir,—Pardon me for adding a few remarks to Mr. Newbury's letter of last week. He still seems to be in the dark as to the nature of the rules of a Friendly Society. The members of such institutions can frame supplementary regulations to meet their own specific requirements; but the majority of rules as embodied in the book they are unable to alter without forfeiting the title of a Friendly Society. One of these unalterable decrees is the laws relating to the ills maternity is heir to, and in constructing it the Government have shown their wisdom and their consideration for all parties concerned. I have carefully examined the matter, and having based my calculations upon statistical reports, am fully satisfied that could we make the alteration as suggested by the "ladies' champion," we should find in a few years that three-fifths of our female members would draw double the amount of their subscriptions to provide the necessary indulgences for these happy events, which would prove anything but so few and far between as I think your correspondent imagines. The only remedy is a special provision as suggested. The members of this fund are entitled to free medical advice and medicines in cases of slight indisposition; it is as equally assured to them as the pecuniary benefit, though the latter cannot be obtained unless the member is "laid up." The rule as quoted by Mr. Newbury in no way contradicts this statement. Like your correspondent, I am ignorant of unlawful *manly* sports—the second adjective is a redundancy of his own. These accidents will not average more than one in a hundred of our male subscribers, and will be exceptional cases, while the maternity calls after a time will to a dead certainty affect some 60 or 65 per cent. of our female members; and it must be borne in mind that the fair sex comprise four-fifths of the club at the present moment. The London District Company employ 116 clerks, of whom 55 have already joined the fund. Mr. Newbury has not forgotten to enumerate as one of the advantages of the institution the facilities it affords of becoming acquainted with our fair fellow clerks, and with preternatural sagacity scents matrimony in the distance. This is an advantage that had hitherto escaped my attention, though I can bear testimony to the business-like qualities and general attractiveness of those ladies who compose the board of management of the fund. In laying these statements before your readers I must entirely disclaim any personal feeling in the matter to Mr. Newbury. He saw what he considered defects, and wished to see them remedied; but was imperfectly acquainted with the nature of these supposed drawbacks. His explanations tended to mislead your readers, and were not in many instances in accordance either with logic or the facts of the case. Many of the objections he urged have been explained away; the others are incidental to every friendly society.

London, March 23rd, 1864. One of the Least.

To the Editor of the Telegraphic Journal.

Sir,—Although a warm supporter of the resolution condemning the above society on account of the technicalities, &c., introduced into its rules, I regret that Mr. Newbury has thought fit to stigmatise the correspondence that has appeared in your journal on the subject as "a useless controversy." I think it is rather to be regretted that your correspondents have not been

more numerous, inasmuch as the publication of a correspondence must, if it excites discussion, criticism, and reply, tend to bring out the true state of feeling with regard to a subject; and this testimony of persons immediately interested in the matter is far more valuable than the *ex-parte* assertions of "A Shareholder" and others. Neither can I attach so much importance as Mr. N. appears to do to the paragraph respecting "accouchments." To the best of my knowledge there are very few married ladies in the service of the telegraph companies, and on such "happy occasions" as accouchments husbands are (or ought to be) always willing to meet the incidental expenses, without applying to a society. Great objection is taken to the exclusive character of the certificate to be signed before enrolment, and more especially to the preliminaries to be observed before obtaining relief in cases of sickness. It is well known that all young men are adverse to anything like ceremony, and would, in many cases prefer incurring expense and inconvenience to waiting upon a "minister or magistrate," who might not at such times be the most civil of functionaries. As Mr. N. suggests, the district superintendent would be the most competent judge, he generally being in possession of accurate information. Cannot something be done, Sir, to remedy the defects complained of? Would it not be advisable on the part of the management of the Telegraph Clerks' Provident Fund to invite suggestions from all quarters, and then appoint a committee of inquiry—chosen from those interested—to report upon the best method of modifying the rules accordingly? If this be done, we shall have no more of the jealousies and rivalries which are said to prevent the employés of the different companies from becoming members.—I am, Sir, your obedient servant,

ONE OF THE MANY.

March 23, 1864.

TELEGRAPHIC NEWS.

MR. STANLEY R. BENNETT, of 31, Nicholas-lane, Lombard-street, the professional accountant of the Mediterranean Extension Telegraph Company, has entered into partnership with Mr. W. P. Gaskell, of Bucklersbury, as public auditors.

IMPORTANT SALE.—The collection of pictures, works of art, antiquities, &c., of the late John Watkins Brett, Esq., will be sold, at the rooms of Messrs. Christie, Manson & Woods, 8, King-street, St. James', on Tuesday, 5th April, and following days.

THE TELEGRAPH CLERKS' PROVIDENT FUND.—We have to announce that the British and Irish Magnetic Telegraph Company have given a donation of £15 15s. towards the above fund, and that the Messrs. Rothschild have also subscribed the sum of £10 10s. towards the same object.

MALTA AND ALEXANDRIA CABLE.—It is with the greatest satisfaction that we announce the restoration of the Malta and Alexandria cable, and the opening of the line for public business. We trust that for the future a properly-fitted vessel will be provided, and kept at a convenient port, for the purposes of repair. Surely the loss sustained by the many weeks the cable has been inoperative would have been more than ample to cover the expenses which the maintenance of such a vessel would involve.

CAPE CLEAR TELEGRAPH STATION.—On the 20th instant a large tug steamer, called the Flying Childers, arrived at Cape Clear. She is intended to intercept the American steamers on their homeward passages, and to take the telegrams they bring. This spirited enterprise of the Magnetic Company will, we hope, help to ensure early American news for the public. Despatches by the City of London, landed at 10.40 a.m. on Wednesday, at Cape Clear, were published in the second edition of that day's *Times*

SOUTH AUSTRALIAN TELEGRAPHS.—The number of messages sent through the South Australian Telegraph in 1863 was 86,851, and the receipts £9,885 4*s*. 7*d*. The number of transmitted messages in 1862 was 76,725, and the receipts £8,047 7*s*. 7*d*.; hence the increase of 1863 on 1862 was 10,126 messages, and £1,337 17*s*. in receipts.

THE ATLANTIC TELEGRAPH COMPANY.—We believe that the great improvements effected, the increased knowledge and experience gained of and in the science of telegraphy, will lead to magnificent results, beyond any conceptions yet formed, even in the minds of the most sanguine friends of electrical advancement, and that the exigencies of commerce and civilisation will cause the Atlantic to be traversed by not only one, but by several cables.

DR. ESSELBACH.—The following is an extract from a private letter from Bombay, per the last mail:—"I am sorry to tell you that poor Dr. Esselbach either committed suicide, or fell overboard, a few days before we arrived (in the Assaye). For some time he had been suffering from fever, and had been delirious, but the day the cable was laid between Guadur and Kasab he appeared better. Everyone was so excited over the cable that no one watched him. He was seen wandering about the deck for some time, and afterwards missed. I think that there can be little doubt that he threw himself overboard in a fit of insanity, resulting from the fever. He will be much missed. You would be astonished at the number of things he got at each station for our comfort and amusement."

THE UNITED KINGDOM TELEGRAPH COMPANY.—The above company announce that stations will be shortly opened at the following towns:—Arbroath, Bristol, Cardiff, Dundee, Edinburgh, Exeter, Gloucester, Glasgow, Greenock, Hartlepool, Leith, Newport, Paisley, Perth, Plymouth, Shields, and Swansea.

MISCELLANEA.

CHEAP TELEGRAPHY.—It is now an established fact that a decreased tariff means an increased traffic. Lower the duty on any article of consumption, and the increased demand for it will more than compensate the revenue for the reduction of duty. High fares are always unproductive to a railway company. Excursion trains are invariably crowded by a class of travellers who would never travel at all, or very rarely, if it were not for the attraction of low fares. A newly-constructed railway is sure to create for itself a traffic, both in goods and passengers, which did not previously exist. No better illustration of this principle can be brought forward than the present penny postage. With a postage traffic of tenpence the number of letters sent was exceedingly limited, and mercantile and business transactions were cramped and retarded; and to nothing is this principle so peculiarly applicable as the electric telegraph. There can be no doubt that, from the high rate of charges for the transmission of messages, the great mass of the people were for a long time excluded from the daily use of the telegraph. The community at large had no more idea of sending a telegraphic message, except on some very extraordinary occasion, than they would have of writing the number of letters they do if the old rate of postage was in force. Still, the use of the telegraph, although considerable reduction in the prices has taken place, is not familiarised to the minds of the masses, except as something to fly to on an emergency; the excess over the shilling excludes it from being so extensively used as it ought to be. What is wanted is, to bring the telegraph within reach of the great mass of the middle classes, who would use it if the charges were from sixpence to one shilling, or even less for short distances, and for a certain class of messages. When Mr. Thomas Allan first proposed a cheap system of telegraphy he found but little favour or encouragement. It is now, however, clear that cheap telegraphy is feasible, and that it is remunerative also, as evidenced by the rapid extension of the shilling system in England.

POLICE TELEGRAPH.—Captain Charles Hodgson, the Superintendent of the City of London Police force, speaking of the value of the telegraph for police purposes, states:—By its means, information is immediately transmitted from the several divisions of the chief offices of all occurrences of an important character, of which particulars were, formerly, only supplied every twenty-four hours. So, likewise, any matter of which it is desirable to send notice speedily to the different stations, is now telegraphed, instead of being sent round in writing by a messenger—a course that formerly occupied about two hours. The telegraph is also found very convenient in promptly obtaining from a division any particulars required relating to matters under investigation at the chief office. On the occasion of fires or other unforeseen emergencies, the telegraph has been found especially useful, not only in conveying the information from station to station, but in enabling the officers to collect from all the stations the requisite number of men, without denuding the streets in the immediate neighbourhood of the occurrence of the constables in charge of beats. As an illustration of its value in this respect, I may instance the occasion of the great fire in Tooley-street, when London-bridge and the city side of the river were, for a considerable period, occupied by a vast and excited crowd, which required the greatest exertion of police authority to control, and, through which, only by the greatest effort could the circulation of traffic be maintained. The large number of the City police so engaged were drawn from the several divisions by a series of telegraphic messages, as the increase of the fire, and the accumulation of spectators, made hourly additions to the strength of the police necessary. A further, and by no means unimportant, aid rendered by the police telegraph, is in the general facility it affords to officers in charge of divisions of conferring with the chief office on matters presenting unusual difficulties, and of communicating with the superintendent, at his residence, at any hour of the night. For these reasons I consider the telegraph most valuable to the force, in economising time, and giving to its officers more direct control over its resources.

ELECTRO-GALVANIC CLOCKS.—The *Malta Observer*, of the 22nd February, says:—"It affords us much pleasure to notice the erection in this City of several public time-keepers, placed within very handsome lanterns, and illuminated by gas at night-time. A great boon has already been conferred upon the public by having these clocks at the landing places—the Custom House, Marina, and at Marsamuscetto Gate—localities in which the want of a time-piece was often and greatly felt; and we are pleased to observe that the electric clocks in these convenient localities are placed within a suitable height, so as to be easily noticed by any passer-by. Another electric clock had been put up in front of the Main Guard at an elevation of about 25 feet or more, where it certainly appeared to every one rather small and insignificant; but we are glad to see that his Excellency the Governor ordered its removal from that inconvenient height, and instructed Mr. Rosenbusch to put it up in the same locality at an elevation of about ten or twelve feet from the ground, where certainly it will be most useful and form at the same time an ornament to the Main Guard Station itself. It is proposed to place similar electric clocks at the following places:—The Palace of Justice, Union Club, Porta Reale Gate, Peninsular Company, and the Market. We heartily congratulate Mr. Rosenbusch upon the success he has achieved in this respect, and hope that he will be equally successful in all his future undertakings. Great credit is due to him for

having started the proposal, the introduction of electric clocks being yet very limited. We propose on another occasion to give some information as to the simultaneous working of these clocks, and show how the regulator clock at the Palace (made by the far-famed Brégnet of Paris) sends an electric current once a minute, and how this flash of lightning swifter than thought moves on the fingers of all dials in the gas lanterns. We are happy to add that his Excellency the Governor has really introduced a most novel, beautiful and useful thing in this city, and we sincerely hope that the time will not be far off when every commercial office, nay every man's house in Valletta will have an electric current sent from the Palace, which will record itself on a clock to keep time simultaneously in many hundreds of others, and require no winding up."

Persons unqualified for Telegraphy.—There are many persons who seem totally incapable of acquiring a knowledge of the art of telegraphy, sufficient for practical use, while others, and especially young persons, will acquire it even in the short space of a fortnight, sufficiently to transmit and receive dispatches with considerable facility. A ludicrous example of this lack of ability to operate this simple apparatus came to our knowledge quite recently. A middle-aged man, employed upon one of our rail-roads, as depôt-master and telegraph operator, found great difficulty, after two years' experience in operating the instrument, and this inability extended to his reading, as well as his transmitting dispatches. Upon one occasion, he rushed out of his office in a great state of excitement, and informed the conductor of a train, which had just arrived at his station, that he had just received a dispatch stating that the —— train had broken both driving wheels, and was badly smashed up; no more trains must post until further orders. The conductor, who was able to read the telegraphic characters, went to the instrument, and, drawing out the paper, read the following dispatch:—"Ask the conductor of the Boston train to examine carefully the connecting rods of both driving wheels, and, if not in good condition, to await orders." The conductor, having made the examination in company with the engineer, and found all right, gave the order for the train to move on, to the infinite astonishment of the *soi-disant* operator, who never was able to find out why the conductor had the temerity to order the train to go on under such grave circumstances. In the same village where this *reliable* operator is employed, there is another telegraph office, where the ordinary telegraph business is done, and, whenever our friend receives a call upon his instrument, he gives the signal to go a-head, and, after receiving the dispatch, takes it to the operator at the other office, to have it translated for him. Not long since, he rushed into the office with a strip of the telegraph paper in his hand, and cried out, "I want you to read this for me, quick; I expect there's some awful accident on the road, the operator rattled away so fast when he sent it." The operator took the strip, but, to the dismay of the nervous visitor, a large portion of it had been torn off by a dog who was attracted by its singular appearance, as it streamed behind him while he flew along, and the part which remained, contained only these words:—"Good morning, Uncle Ben. When are you ——." The dog had swallowed the rest.—*Prescott's History of the Electric Telegraph.*

Remarkable Telegraphic Experiment.—Being at Paris some years ago, I was engaged to share with M. Leverrier, the celebrated astronomer, and some other men of science, in the superintendence of a series of experiments to be made before committees of the Legislative Assembly and of the Institute, with the view of testing the efficiency of certain telegraphic apparatus. On that occasion, operating in a room at the Ministry of the Interior appropriated to the telegraphs, into which wires proceeding from various parts of France were brought, we dictated a message, consisting of about forty words, addressed to one of the clerks at the railway station at Valenciennes, a distance of 168 miles from Paris. This message was transmitted in two minutes and a-half. An interval of about five minutes elapsed, during which, as it afterwards appeared, the clerk to whom the message was addressed was sent for. At the expiration of this interval the telegraph began to express the answer, which, consisting of about thirty-five words, was delivered and written out by the agent at the desk, in our presence, in two minutes. Thus, forty words were sent 168 miles, and thirty-five words returned from the same distance, in the short space of four minutes and thirty seconds. But, surprising as this was, we soon afterwards witnessed, in the same room, a still more marvellous performance. The following experiment was prepared and performed at the suggestion and under the direction of M. Leverrier, and myself:—Two wires, extending from the room in which we operated to Lille, were united at the latter place, so as to form one continuous wire, extending to Lille and back, making a total distance of 336 miles. This, however, not being deemed sufficient for the purpose, several coils of wire wrapped with silk were obtained, measuring in their total length 746 miles, and were joined to the extremity of the wire returning from Lille, thus making one continuous wire making 1,082 miles. A message consisting of 282 words was then transmitted from one end of the wire. A pen attached to the other end immediately began to write the message on a sheet of paper moved under it by a simple mechanism, and the entire message was written in full in the presence of the Committee, each word being spelled completely and without abridgement, in *fifty-two seconds*, being at the average rate of *five words and four-tenths per second!* By this instrument, therefore, it is practicable to transmit intelligence to a distance of upwards of 1,000 miles, at the rate of 19,500 words per hour! The instrument would, therefore, transmit to the distance of 1,000 miles, in the space of an hour, the contents of about forty pages of the book now in the hands of the reader! But it must not be imagined, because we have here produced an example of the transmission of a despatch to a distance of 1,000 miles, that any augmentation of that distance could cause any delay of practical importance. Although the velocity of the electric current has not been very exactly measured, it has been established beyond all doubt that it is so great that to pass from any one point on the surface of the earth to any other, it would take no more than an inappreciable fraction of a second. If, therefore, the dispatch had been sent to a distance of twenty thousand miles instead of one thousand, its transmission would still have been instantaneous. Such a despatch would fly many times round the earth between the two beats of a common clock, and would be written in full at the place of its destination more rapidly than it could be repeated by word of mouth. When such statements are made, do we not feel disposed to exclaim—

> "Are such things here as we do speak about?
> Or have we eaten of the insane root,
> That makes the reason prisoner?"

In its wildest flights the most exalted imagination would not have dared, even in fiction, to give utterance to these stubborn realities. Shakspeare only ventured to make his fairy

> "Put a girdle round the earth
> In forty minutes."

To have encircled it several times in a second, would have seemed too monstrous, even for Robin Goodfellow.—*Dr. Lardner on the Electric Telegraph.*

REMUNERATIVE SPEED ON SUBMARINE CABLES.

THE speed of transmission through submarine cables has been greatly accelerated in consequence of the great improvements which have been effected in galvanic batteries, in the conductivity of copper, in the insulating material, and in signalling apparatus. The following record of the number of words transmitted through various submarine telegraphs in their submerged and working state will enable our readers to compare the past and the present attainable speed:—Through the Varna and Balaclava cable, 310 nauts in length; copper conductor, $\frac{1}{16}$-inch in diameter, covered with gutta-percha to No. 1 gauge; 5 words per minute. The Atlantic Telegraph cable of 1858: length, 2,500 miles; weight of copper per knot, 107 lbs.; weight of gutta-percha per knot, 261 lbs.; maximum speed, 2½ words per minute. The Red Sea cable: length, 730 knots; weight of copper, 180 lbs. per knot; weight of gutta-percha, 212 lbs. per knot; rate of speed, 7 words per minute. The Malta and Alexandria cable: length, 1,260 knots; weight of copper, 400 lbs. per knot; weight of gutta-percha, 400 lbs. per knot; speed attained, 10 words per minute. The new Atlantic cable: length, 1,880 knots; weight of copper, 300 lbs.; weight of gutta-percha, 400 lbs.; rate of transmission experimentally ascertained by Mr. C. F. Varley, electrician to the Electric and International Telegraph Company, and Professor Thomson, F.R.S., to be 8 words per minute, and this high speed may be much increased by a proper system of abbreviation and coding.

The Morse instrument employed for the measurements of speed, as above enumerated, has been greatly improved within the last few years, and we believe that other valuable modifications are being carried out which will still render the apparatus far more efficient and rapid in its action. The Hughes instrument, now about being employed on the Persian Gulf cable, is exceedingly well adapted for working long lines of submarine telegraphs. It has the great advantage that it prints one letter with every wave, or with every current. We ourselves have had frequent and ample opportunities of witnessing the great rapidity and accuracy with which the machine worked at the rate of 16 words per minute through a cable which would only permit of 6 or 7 words per minute being sent through the ordinary Morse. There are other instruments capable of rendering efficient service, and we have no doubt the directors and advisers of the Atlantic Telegraph Company will ensure the employment of those which will be found the best adapted for the development of the great undertaking.

Having endeavoured to place before our readers a brief history of the progress which has taken place in the science of submarine telegraphy, we shall now take into consideration the commercial aspect of the Atlantic Telegraph undertaking. Circumstances combine to render the prospects of the Company brighter and more promising day by day—inland telegraphy becomes more remunerative—an important submarine cable successfully submerged in the far East—the Malta and Alexandria cable restored—public confidence re-established, and more than ever impressed with the value of telegraphic communication. We have already stated that the new cable to cross the Atlantic is to be constructed to ensure a working speed of 8 words per minute. If we were to reduce the attainable speed of 8 words even to 6 words per minute, the full employment of the line would render the undertaking exceedingly profitable. The following would be the result:—Six words per minute would give 360 per hour, or 8,640 per day of 24 hours, which it would be necessary to occupy in consequence of the vast amount of business which would have to be transmitted. Allowing 300 working days in the year, the number of words which it would be practicable to transmit would amount to 2,592,000, or 129,600 messages of 20 words each per annum, being at the rate of 432 per day, which, at £5 per message, would yield a revenue of £648,000, and, after allowing out of this sum £216,000 for contingencies, there would remain a net revenue of £432,000, as the result of 300 days' operation, at the end of the year. The disbursements, it is believed, may be estimated as follows:—Working charges at stations in Ireland and Newfoundland, and office expenses in London, £15,000; dividend of 8 per cent. on preference stock, £48,000; 5 per cent. interest on bonds, £5,000; and 4 per cent. dividend on old stock, £24,000; amounting in the aggregate to £92,000, which, being deducted from the net revenue as above specified, would leave a balance of £340,000, which would pay an additional dividend of more than 25 per cent. upon the whole capital, old and new, of £1,300,000, and making up the dividend upon the preferential stock 33 per cent., and on the old stock 29 per cent., leaving a surplus for contingencies of £40,000, besides the subsidies for 25 years, each from the English Government, £20,000 per annum, and the United States, £14,000 per annum, and the discounts agreed to be made by other telegraph companies on all business passing over their lines to and from the cable. That the above estimated amount of income on a line capable of transmitting 8 words per minute will be realised, the operations of the Malta and Alexandria line afford unquestionable proof. In the above estimate we consider that we are far below the actual receipts which may be reasonably anticipated from a line uniting the vast social, commercial, and political interests of the Old and New World. In conclusion, we most heartily congratulate the directors and the shareholders on the present prospects of the Company.

BONELLI'S ELECTRIC TELEGRAPH COMPANY.

UNTIL society attains to that Elysian condition when each member of the community shall feel another's good to be his own; until men, abnegating self, labour for the public weal; so long will competition prove the only means of restricting monopoly, and ensuring to trade and commerce due development. The inventive faculties of man seem to receive a stimulus to exertion in the contemplation of how best to supersede the devices and productions of his fellow, and we accordingly find improvement succeeding improvement, until the old world of inventions passes away before the new era, to disappear in its turn. It is well. The onward march of civilization opens up requirements undreamt of by philosophers, extatics, or poets; and when we find this ever-yielding law of progress suspended, when science is at a standstill, when art declines, and when the multitude of tributaries to national wealth cease to flow, then—but not till then—dare we murmur. We live for the future, and hail with welcome every advance towards perfection in the applications tending to human convenience and felicity. Science

has surrounded the peasant of the present day with greater comforts, personal and domestic, than were enjoyed by the peer, yea, the prince of the last generation. It has made steam our handmaiden, the earth our messenger, and lightning, once a terror, is now a voice which enables us to communicate our thoughts and emotions to distant friends, and to receive expressions of their sympathy, be they at the ends of the earth, in a second, thus obliterating time and space.

The various applications by which we are now able to effect these latter results, have been brought from the simple to the compound, from the incomplete to the comparatively perfect form in a few years; and as improvement has succeeded, step by step, in supplanting old instruments, the interested outcry against innovation has been raised, and we know of valuable inventions suppressed, lest rivalry should induce a disastrous competition. Progress may be retarded, but it cannot be seriously influenced by these petty devices of the shortsighted and the ignorant; and now, notwithstanding many adverse circumstances encountered, we have to announce the successful establishment of a company, to employ the beautiful transmitting and printing telegraph of the Chevalier Bonelli. This project, which has been nurtured by Mr. Henry Cook since the year 1851, has now assumed a character and importance demanding more than a passing notice. The Company, which was originally established with a capital of £25,000 for the purpose of effecting telegraphic communication between Manchester and Liverpool, proved, beyond expectation, the excellence of the Bonelli system. The directors, encouraged by the success which has hitherto attended their transactions, have determined to extend their operations to the principal centres of commercial activity, and with this view have issued new shares, raising the capital of the Company from £25,000 to £250,000, which will enable them to complete arrangements with Chevalier Bonelli for the entire patent-right for the United Kingdom, and to commence operations on the proposed enlarged footing.

It is confidently expected that by thus extending to all the important districts of England the advantages, practical and economical, possessed over every other system of telegraphy hitherto in use by the Typo-Electric Telegraph, and through the reduction of the tariff, which its employment allows, to a uniform rate of sixpence per ordinary message of twenty words—placing the boon of telegraphic intercommunication within reach of the masses—new and boundless sources of business, and, consequently, of profit to the shareholders, will be created, while to all who already use the Electric Telegraph will be secured, for the first time, that rapidity, correctness, and punctuality, which, from the nature of the agent employed, the public had a right to expect, but which has never yet been practically attained.

The prospectus of the Company is before us, and the recommendations of their system are thus set forth:—

First. Each message is printed by the very act of transmission, in clear Roman characters, and as so transmitted is delivered, without further process, to the receiver, thus absolutely excluding all possibility of error from any source existing between the sender and the receiver.

Second. The extreme rapidity with which messages can be transmitted in succession, resulting both from the nature of the apparatus and its non-liability to error, not only allows these instruments to keep pace with the largest amount of business within the experience of existing establishments, but places them beyond all likelihood of being overtaxed, even by the increased pressure of work that must inevitably ensue from a uniform sixpenny rate for the ordinary message. This rapidity and certainty of working applied to the requirements of journalism must naturally produce results even more marked; and it has been proved by practice that a speech which, by the ordinary instruments occupied six and a-half hours in transmission, could, with an equivalent staff, be printed off by the Bonelli Telegraph, in an immediately legible form, in the space of one hour and a-half. No less emphatically does the instrument recommend itself to members of the Stock Exchange, to whom it ensures that absolute accuracy, united with exemption from delay in communicating with their correspondents, which cannot be invariably counted on under existing systems.

Third. The automatic nature and simple working of the Bonelli instrument, renders it independent of specially trained, and therefore highly paid, manipulators.

Fourth. The necessity to which all other telegraphic establishments are exposed, of increasing the staff of operators, in proportion with the augmentation of business, thus involving an enormous and comparatively unprofitable expenditure of capital, or the forfeiture of public patronage, does not exist where Bonelli's instruments are employed, and consequently, all increase of business must prove almost absolutely clear profit.

In submitting the claims of this Company, the directors have expressed their confidence in being able to supersede the old systems of telegraphy as completely and as universally as steam and the rail have supplanted the stage and the post road. The Company has been received with considerable favour by the public, which augurs well for all parties interested in the success of the undertaking. When the projected lines are completed, this Company will be able to compete with existing establishments, and thus determine the relative merits of the different transmitting apparatus, and, as they propose a very great reduction in charges, cheapen telegraphy, and bring it into more general use.

There is scope enough in England for the extension of the telegraphic enterprise; hence we note with satisfaction the advent of the new company. In 1850 the number of messages transmitted in this country was 64,734; in 1862 they had increased to upwards of 2,000,000, or 2,300 per cent. This vast increase is to be attributed mainly to the reductions which have been made from time to time in the tariffs, and we fully anticipate that when the use of the wire is placed within the reach of the masses, the telegraphic system will be as generally adopted as have been the schemes of Rowland Hill.

FAULTS IN INSULATION.

We quote the following remarks upon the above subject from the Government Report, at the request of an esteemed correspondent. The suggestions of the writers deserve every consideration on the part of those engaged in the manufacture and management of submarine cables. The experiments prove the necessity of having a considerable portion of the ends of a submarine cable furnished with the best material, and the most perfect insulation:—"I will next consider the action of a battery upon these small faults, and the importance of this point cannot be overrated. First under this head I will examine the degree in which faults are subjected to the action of the battery, according to their position in the cable, whether near the battery, or at a distance from the battery. The internal wire of a submerged cable, charged by a battery, may be considered as one source of electricity; the water surrounding the cable as a second source of electricity; the potential of the latter source being zero. The potential of the internal wire of the cable, when perfectly insulated at all points, is equal to the potential of the pole of the battery with which it is in connection. In a well-insulated cable this is sensibly the case, when one end of the wire is connected with the battery and the other end insulated. When, however, the other end of the wire is connected with earth (as when signals are being sent), the potential of the internal wire varies at every point. Close to the battery, the potential is still equal to that of the pole of the battery with which it is connected; close to the end of the wire which is connected with earth, the potential at the wire is zero. At intermediate points the potential diminishes in direct proportion with the distance of each point measured by electrical resistance from the pole of the battery; thus, midway the potential is half that of the pole of the battery, and so on. This law obviously only holds good so long as the fault offers a resistance, as large as compared with that of the portion of conducting wire between the fault and the end connected with earth. Some slight divergence from the law described will also occur in a cable which is not perfectly insulated, but which is equally insulated through its entire length, as in the case of a sound gutta-percha cable. It is not now, however, necessary for my purpose to investigate the precise sequence of the potentials at the consecutive points of such a cable, although this may some day become a valuable test. My wish now is only to show to what extent a battery extends its full power on defective

portions of a cable at different points of its length. From what has just been said, it results that if 100 cells are used in signalling through a cable 500 knots long, a fault which exists midway will only be subjected to a statical power equal to that of 50 cells, applied directly at the spot where the fault exists; and a fault 400 knots distant from the battery would only be subjected to a statical power equal to that of 20 cells. When, however, signals are sent from the opposite end, this latter fault will be subjected to a power equal to that of 80 cells. When there are several faults in a cable, the potential at different points of the wire no longer varies in direct proportion with the linear distance from the pole of the battery, as is the case in a sound uniform cable, but diminishes rapidly after each fault; the larger the fault, the greater the diminution of potential in the wire beyond it. Each fault, as it were, protects those parts of the cable beyond it from the full action of the battery, and thus it may happen that mending one fault close to shore may cause a fault at a greater distance to deteriorate rapidly, under the action of a battery which had not before injured it (assuming, for the moment, that the action of a battery is detrimental). From the above considerations, we see that a fault near one end of a cable may be uninjured by signals sent with an equal battery in the opposite direction. We also see that a cable is more severely tried in some respects at all points distant from the shore, when tested for insulation, than when used to transmit signals, the battery remaining the same."—*Fleeming Jenkin, Esq., C.E.*

"We obtained similar measurements of 554 miles of cable, of which, 154 miles consisted of the least perfect cable, and the remaining 400 was the length newly manufactured of standard wire. The results were very different, according as the standard length, which is well insulated, was nearest the battery power, or farthest from it. The following are the reduced details of the two cases:—1st standard wire at home end, entering current, 1·000; signal fork (far end), 0·775; leakage (circuit complete), 0·245; leakage (far end free), 0·798. 2nd standard wire at far end, entering current, 1·000; signal fork (far end), 0·485; leakage (circuit complete), 0·515; leakage (far end free), 0·937. These measurements show that the greatest advantage is gained out of the best specimens of cable by having them nearest to the source of electricity, or at the shore end. The advantage gained in the above two modes of arrangement, is as 755 to 485, or as 1½ to 1. The good specimens of 400 miles is at the bottom of Niagara coil, and comes out last. Should her portion of the cable become so exhausted that this will become the first length from Newfoundland, it will be in the best possible position. Should the first lengths from either shore consist of the worst specimens, they will be in the least advantageous position."—*C. V. Walker, Esq., F.R.S.*

THE INDIAN TELEGRAPH.

THE tame lightning, obedient to the hands that drew it down from heaven and manufactured the long wires for its path, begins to cross and recross the earth in every direction, bearing our instantaneous messages. Long ago we ought to have been in momentary communication with America—the electric telegraph *has* made the continents speak together; but, thanks to the lingering civil war, America and Europe are still as far apart as if Wheatstone's wonderful invention were yet to be proclaimed. But elsewhere good work is doing. The snake-like cables are stealing over the lands and under the seas, linking countries and continents closer and closer together. The Indian telegraph will soon be an accomplished fact. The line is laid, by the last despatches, all the way from Kurrachee to Mussendom; and the steam-consorts of the expedition had towed the Kirkham and Marian Moore empty to Bombay, to fetch up the Tweed and Assaye, which had on board the remaining 730 miles of the cable for the Arabian Sea. The line is thus laid already from the mouth of the Indus to Ras Noo on the Mekran coast, and from Ras Noo to Mussendom—altogether about 360 miles, and some of it over the worst part of the sea-bottom. It has gone down to its bed in those astonished waters with undiminished electrical insulation; the messages go sharp and crisp to Kurrachee; and thus far the wonderful undertaking is a complete success. It has yet to thread the Persian Gulf to Bussorah, thence to find its way among wild tribes and ruined cities to Baghdad; and when the line shall be thus far finished, India will be but a few hours distant from England—indeed, as the sun is earlier there than here, we may some day obtain a message rather before the minute at which Calcutta or Madras despatched it. What miracle in old religions is really greater? The accounts of the successful expedition tells us of the astonishment of the savage Beloochees and Arabs along the Mekran, at this marvel of a blue spark flashing for the Sahebs to Indus and back again in the time that it takes to "smoke a hookah." There is a town upon the sandy shore there called Gwadur, at which one station of the line has been fixed. No sooner was it landed there, than the people of the surrounding country flocked down to hear and talk of the Feringhee witchcraft. Chiefs of the Beloochees, Muscatees, and Heratees, with their retainers, trod upon each other's toes in their eagerness to see "the strings" at work. Gwadur has deliberately given up the idea that Mahomet taught everything that could be known; Gwadur "sits upon the carpet of astonishment, and chews the betel-nut of meditation." It is only to be hoped that the roving Kurds and Iranistan robbers about the head of the Persian Gulf, will be afflicted in the same way—with wonder, instead of cupidity or fanaticism; then the Arabian sea telegraph will, before long, link all the systems of Europe with that which binds together the capitals of India.

Telegraphic engineering has a curious history, and few passages in it are more creditable than the way by which the lines were established which we shall join when the wire passes down from Kurrachee to Bombay. Thanks to Lord Dalhousie, and to his scientific lieutenant, Sir William O'Shaughnessy, Bombay, Calcutta, and Madras have long been united by the electric line. But it was a singular problem that presented itself to that clever Deputy Assay-Master of the Mint when, with his chief's encouragement, he turned his hand to creating telegraphs for India. Let no one suppose that it was merely an affair of constructing a battery, laying the wires, nominating staff, and then the thing was done. In the first place, Sir William discovered that the air of India is in a state of constant electrical perturbation of the strongest sort, so that the instruments then mounted went into a high fever, and refused to work. Along all his north and south lines, he found a current of electricity constantly passing, which threw the needles out of gear and baffled signallers. Moreover, the tremendous thunder-storms ran up and down his wires, and melted his conductors; the monsoon-winds tore his teak-posts out of the sodden ground, and elephants and buffaloes trampled the fallen lines into kinks and tangles. The cotton and rice boats, "kedging" up and down the river, dragged his subaqueous wires to the surface. These were some of the serious Indian difficulties; but over and above them, which he met in various and ingenious ways, there were *quasi*-ridiculous obstacles. Wild pigs and tigers scratched their skins against his posts in the jungle, and porcupines and bandicoots burrowed them out of the ground. The Delta aborigines carried off his timber supports for fuel, and the wires or iron rods upon them to make bracelets and Hindoo smitheries. If those left them alone, kites, fishing eagles, and hooded crows came in hundreds and perched upon the line, to see what on earth it could mean; and sometimes after a thunderstorm, when the wires were wet, were found dead by dozens, perished through their curiosity. Monkeys climbed the posts and ran along the lines, chattering, and dropping an interfering tail from one wire to the other, which tended to confound the conversations of Calcutta. Parrots hung upon one string by the beak and another by the leg, with the same contempt for electrical insulation; and in one village the complacent natives stretched their fishing-lines to dry upon them. Sir William O'Shaughnessy had to encounter and conquer all these odd and unexpected mischances, before he proved, by his experimental line and self-invented machines, that all the peninsula could be covered with telegraphs at £500 per mile. To him in the first place, and to Lord Dalhousie in the next, it was due that the idea was carried out. In 1856, there were 4,000 miles of telegraph stretched over India—some upon bamboo posts, which bent to the storms, and thus defy them—some, as in the Madras presidency, upon monoliths of granite—all serviceable; and in the mutiny they proved to be worth ten times their cost.

The telegraph, indeed, so far saved India, that it spared us the disgrace of being beaten down to our ships and the sea-coast, during the awful hour of suspense while succour was coming. The Anglo-Saxons were quickly warned, by the wonderful "vidette" they had introduced, of the approach of the frantic soldiery, and so found time to gather in little knots, and present the front that defended station after station. But for the telegraph, established in spite of all these curious obstacles in the animal and atmospheric world, the first news of the rebellion, even in Agra as at Delhi,

might have been the inroad of savage Mussulmans proclaiming their message by the colour of their hands. The electric spark ticked the word "rebellion" over English India, and the Englishmen stood on their guard. These days are past, however, and the telegraph lines now stand ready to be linked with ours in Europe, as part of a united network which will help to bind the world together. Already, a company proposes to carry a communication to Rangoon, Singapore, and the north coast of Australia southwards from Calcutta, and to Hong Kong and Manilla northwards. As lines increase, they breed lines; new trials and experiments avert failures; habit of such lightning-like ease of communication makes it indispensable. When Calcutta talks to London at breakfast time, and gets her answer before tiffin, we shall not wait much longer ere Puck's girdle shall be put round the world in less than "forty minutes."—*Daily Telegraph.*

THE EARTH AS A CONDUCTOR.

By G. B. Prescott, Esq.

We will here say a few words upon the important part played by the earth when it is employed as a conductor in the operations of electric telegraphy. We have already seen that the idea of employing the earth as a conductor between two telegraphic stations, realised for the first time by Steinheil, had permitted the suppression of one of the conducting wires, and thus the realization of great economy and simplicity in practice. It was at first supposed that the ground played the same part as the conductor for which it was substituted, and that there was established between the two poles of the battery placed in communication with the earth, even when they were at a great distance apart, a veritable electric current, transmitted through all the interposed conducting matters, and which the earth always contains in greater or less proportion. The terrestial globe cannot be considered as being in its nature so perfect a conductor as a metal, but its bad conductibility is found to be more than compensated by the immensity of its section. We may therefore consider the earth as presenting a null resistance to conductibility. MM. Bréguet and Mattencci, by various experiments, found that where the current went by the copper wire from Pisa to Pontedera, and returned by the earth, its intensity was the same as when the two poles of the battery were immediately united by a single copper wire as long as that by which the two stations were connected. This experiment, and a great number of other similar ones, enable us therefore to admit that the resistance of the earth to electric conductibility is null. Electric currents, we must admit, are able to cross each other in all directions, and at every instant, without affecting each other; and we must suppose that, between two stations very far apart, such as New York and Buffalo, there is a series of decompositions and recompositions of all the interposed molecules of water, and that the positive electricity, for example, that is introduced into the ground at New York cannot be neutralized except by the negative arising from the same battery, but brought by the telegraph wire into the ground at Buffalo, a neutralization going on from molecule to molecule, through all the conducting sections that are found in the terrestial globe between these two stations. It is likewise necessary to admit, when the positive and negative poles of several batteries are plunged at the same time in the ground at great distances from each other, that the positive electricity of each pole, in order to become neutralised, seeks for the negative electricity of the pole belonging to the same battery, even though this pole might be much more distant than the negative of another battery. This hypothesis of the predisposition of the two electricities to neutralize each other only when they arise from the same source, appears to us equally contrary to logic and to observation. We must therefore have recourse to another explanation of the part played by the earth in the phenomena of electric conductibility,—an explanation which flows very naturally, from the fact observed by Faraday and Wheatstone with electric cables. This fact is that of a vast reservoir—of a species of drain—which sucks up and absorbs, at the two extremities of the wire, the free electricities which the battery, or any apparatus that is the generator of electricity, sends into it. By the very fact that this electricity is lost or escapes, there is an electric movement, and, consequently, a production of a current. M. Magrini, in experiments made with long, well-insulated telegraph wires, extending from Milan to Menza, had already shown that an electric current might be obtained in a wire of which only one of the ends communicated with a source of electricity, whilst the other remained insulated; but, in this mode of operating, some defect of insulation might be feared. This fear disappears on the experiments of Faraday and Wheatstone. These latter very clearly show us that it is enough to put into communication with one of the poles of a battery, the end of a conductor of very great dimensions, the other extremity of which is insulated, in order that this conductor, in becoming charged, may be traversed by an electric current, the pressure of which is indicated by the deviation of the needle of a galvanometer. The same phenomenon takes place with the earth, with this difference, that the terrestial globe being a conductor of infinite dimensions, the current is able to endure as long as the communication of the pole with the ground takes place.

M. Mattencci, who has greatly directed his attention to the conductibility of the earth, had made the curious remark, that when the electrodes are plunged into the ground to a suitable depth, the resistance of the interposed layer increases exactly with its length, according to the recognized law for ordinary conductors; there is not even any difference, when the layer is very thin, between its resistance and that of the same layer of earth or water contained in an insulated vessel; but if the distance between the electrodes becomes considerable, the resistance of the terrestrial bed diminishes very rapidly; even at the distance of from sixty to one hundred yards, the current ceases to diminish; at greater distances its intensity increases until it becomes equal to that which would be found with the circuit entirely metallic. This result is always verified for distances of ten or twelve miles. The increase of the current with the length of the terrestrial bed is independent of the nature and form of this bed; it was before having arrived at the length of the bed at which the resistance ceases that the influence was observed of the nature and form of this bed over this same resistance.

This observation of M. Mattencci clearly shows us that the earth is able to play two very different parts in the transmission of currents. It is able to discharge the function of an ordinary conductor when the electrodes are very near to each other; and then the resistance, which it opposes to the current, increases with the length of the interposed terrestrial bed; but when the distance between the electrodes attains to a certain limited dimension the earth acts as a reservoir, which absorbs the electricities liberated at each of the poles; its resistance then disappears, and the intensity of the current depends on nothing more than the resistance of the conducting-wire alone; so that the intervention of the terrestrial globe presents the double advantage of permitting the economy of one line wire, and of rendering the current twice as strong as it would be were it made to return by the second suppressed wire. The results obtained by Mattencci in his experiments have been verified by our own in a somewhat different manner. A telegraph line of one mile in length, extending from the counting-room of the Bridgewater Iron Works to the works themselves, furnished with a current of five Daniell's cells, had never worked well, the current being always weak and shaky. We were finally called upon to solve the difficulty, and after satisfying ourselves that the connections were perfect, decided that the earth's termini must be imperfect, not being of sufficient depth to overcome resistance. We accordingly attached a copper wire, and ran it into the canal, when the intensity of the current at once increased to the full amount desired. Subsequently, upon our explaining to Mr. Sprague, the operator, the laws of transmission and resistance—that the resistance of the earth was in the inverse ratio to the surface of the metal buried—he attached a plate of copper to the wire, and placed that in the canal, when he was able to reduce the intensity of his battery one-fifth, and still have a stronger current than before. The difference between what takes place when the electrodes are near together, and what takes place when they are far apart, may seem extraordinary at the first moment; but upon reflection, we easily conceive that in the former case the molecules interposed between the two electrodes, not being so numerous, may constitute the electric chain by the effect of the mutual neutralization of their opposite electricities, which is preceded by their polarization. When the electrodes are very distant this communication between them can no longer take place, and they are then discharged, by means of the bed with which they are in contact, into the entire mass of the terrestrial globe.

Besides, many other facts of a different kind demonstrate that it is not necessary, in order to obtain a current, to re-unite the two contrary electricities produced by the same electrical apparatus,

but that it is sufficient that one of the two electricities be absorbed. Thus it is that when the outer coating of a Leyden jar is placed in communication with the ground, we are able to obtain a discharge in the air similar to a current by furnishing its inner coating with a point.

The part played by the earth in the transmission of telegraphic despatches is, therefore, in accordance with a very great number of phenomena of the same kind, which have demonstrated to us that the propagation of electricity, and consequently the production of an electric current, may take place in a conducting body as well when this body is placed in communication with another charged with an excess of one of the electricities only as when it is found placed between two excesses of contrary electricities. When the terrestrial globe is employed for bringing about the circulation of a current in an insulated conductor, one of the extremities of which communicates with one of the poles of a battery and the other with the ground, whilst the second pole of the battery also communicates with the ground, care must be taken to establish these communications well. With this view, the conducting wires that go to the earth terminate in large metal plates, generally of copper, which are also buried as deep as is convenient in wells, or in the most moist parts of the ground that can be found. The gas and water pipes of towns are advantageously employed for obtaining good communication with the earth; and iron fish-jointed rails are valuable, in country stations especially. Upon nearly all telegraph lines where an intermediate office puts on a ground—that is, puts the main wire in communication with the earth without separating the main line—other stations may, by adjusting their armatures very closely, obtain what is being communicated upon the portion of the line intercepted by the ground. This is owing to the imperfect contact between the ground-wire and the earth, a part of the electric current passing by the ground-wire sufficient to work a delicate relay magnet.

ON MAGNETIC CALMS AND EARTH-CURRENTS.

By Charles V. Walker, Esq., F.R.S., F.R.A.S., &c.

II.

The author uses the word "calm" in a negative sense, "not storm," and states that very few notable earth-currents have attracted attention since the date of his original communication to the Royal Society, which was read on February 14, 1861.

Referring to that communication, he calls attention to the London, Tonbridge, and Dover-London lines of telegraph, making an angle of direction with each other of 149°, and by means of which a few groups of observations were made, from which the prevailing direction of earth-currents was determined to be approximately N.E. or S.W. He wished to multiply these observations and to modify them, which he was well able to do from the circumstance that the Dover-London telegraph wires enter his own private office at Tonbridge, where, by means of the necessary apparatus, he is able at any moment, when the wires are not occupied by telegrams, to obtain possession of the whole wire from end to end, Dover-London; or either section, London-Tonbridge or Dover-Tonbridge, the two former being the limiting lines, or those making the greatest available angle with each other, and the last, which is intermediate, being useful in confirmation of the observations made on the other two.

The telegraph needles have been rarely affected of late, the earth-currents, which form the subject of the present communication, being feeble. In order to their examination, it was therefore necessary to prepare a delicate galvanometer, which is properly connected with the telegraph wire, and furnished with the simplest possible apparatus for bringing it into action whenever occasion serves. It is within arm's length of the author when in his office. The pressing down of a spring allows any earth-current that may be present to enter the galvanometer; a brass plug, placed in holes 1, 2, and 3, gives possession of the whole line, or either of its sections. The needle is deflected on the side marked "up" or "down," according as the current collected is moving up or down the line; and in all the tables given in this communication the letters "u" or "d," placed beside the degrees of deflection, give the direction of the current in the above popular terms. The galvanometer, with its appliances, accompanies this communication, and is placed on the table as *in situ*, and will at a glance give an idea of the arrangement, of which also the author gives a plan.

A table is given of earth-currents collected at Tonbridge in October, 1861, on the lines in question, together with the Meteorological Register of the month. An analysis of these observations follows, included with which is an analysis of all observations of a like character that were made in the subsequent month of November.

A few cases are recorded in which the earth gave no sign of current. No stress is laid on this, because a closer investigation with more delicate instruments might have given positive results.

The contents of the table are divided into *Normal*, *Abnormal*, and *Exceptional*. Out of a total of 276 observations, 230 gave *normal* results, confirming the conclusion already arrived at, that the prevailing direction of earth-currents was approximately N.E. or S.W. Whether one or other of these directions prevailed more or less at different periods of the day did not appear, the observations not being sufficiently consecutive. Father Secchi's views of the relation between meteorological phenomena and magnetic variation are referred to. The author has reason to conceive that sunshine or cloud, heat or cold, influence the relative values of the current collected from different parts of the same district; in connection with which he refers to a group of night observations, which form part of the series made in October, and also to the want of consistency in the relation between two derived currents collected at the same time from different parts of the same plane. He gives a few extracts from the table, showing how very variable are the relations; for instance, 15° : 15°; 15° : 30°; 15° : 35°; 13° : 38°; 18° : 21°; and so on.

Professor Loomis's "Eighth Article" on the subject is referred to; and the correspondence between the results at which he arrives by other processes, and those to which Mr. Walker arrives by the methods herein described, are given.

In addition to the currents whose direction has been already noted, 42 cases occurred of currents which, for distinction sake, are called *abnormal*, and which were equally definite in character. They are found in the S.E. and N.W. quadrants; but the probable place in these quadrants could not be determined with any approach to accuracy from the lack of other lines of telegraph immediately at command. Four diagrams are given in illustration of the *normals* and *abnormals*.

The author mentions that the South-Eastern Railway Company have cordially entertained the proposition, to which he has previously referred, of the Astronomer Royal; and that he is now preparing to erect wires for Mr. Airy, terminating respectively near Dartford and Croydon, and which by combination will give an angle of 36° or 107°, the former, however, being without the range of normal direction. The consecutive observations to be made on these wires promise to be very instructive. The porcelain-ebonite insulator that will be used is described.

Among the 276 October-November observations, four cases occurred which are exceptional, and do not admit of similar discussion. Subsequent observations may explain these.

Next follows a survey of the N. and S. boundaries of a plane, the mean dimensions of which are 56 miles × 20 miles, bounded on the N. by the Thames, and on the S. by the Dover-Tonbridge line of railway. This was accomplished by aid of the earth-plates at Ramsgate and London, to the former of which access was had at Tonbridge, when required, by means of a switch at Ashford junction. A table is given of observations made during November and December, which show that the plane of the current is at least 20 miles wide, and the direction is consistent at either limit of the plane.

Tonbridge, being very nearly midway on a line joining London and Hastings, gave the opportunity of making observations on the whole, or on either half of a same line of country. The results collected in November and December are given in a table, and show a conformity in direction in the whole and in both halves, but a marked excess in value in the London-Tonbridge as compared with the Hastings-Tonbridge section. These differences are considered by the author as probably due to the different geological conditions of the country on either side of Tonbridge. Sections kindly furnished by Mr. Robert Hunt are referred to. These differences indicate the influence of local conditions, as the differences previously mentioned point at the interference of meteorological variations.

In order to satisfy himself that he was dealing with currents collected *boná fide* from the earth, and in no way from the atmosphere, arrangements were made with the clerks at Ashford to detach the observing wire from the earth there when required. A considerable number of observations were made during October, November,

and December, the results of which are tabulated. Whether the current, as shown by the galvanometer, was weak or strong, it in every instance entirely ceased when the wire at Ashford was detached from the earth and held insulated; so that no portion of the result was derived from any other source than the earth. These observations were made at all periods of the day and night, and in all weathers.

Powerful artificial currents were repeatedly made to flow into the earth by the earth-plates, in order to see whether any effects of polarization were produced; but the value of the earth-current, as observed before any such experiment, remained unchanged.

That the currents collected are in no way due to the electromotive power of the earth-plates themselves is shown by the absence of any sign of a tendency for one or other direction. They are independent in character and in value of all such influences. To prevent misconception, a list of the earth-connections used at the several stations that enter into the present investigation is given.

The author considers it may be premature to regard the subject as tolerably exhausted, as far as the means at his command are concerned; but at this moment he does not notice any other salient point within his reach. When the proposed special wires are ready for Mr. Airy, and consecutive observations are made and compared with the march of the magnetometers, the subject will be within the reach of the able hands of Mr. Airy; and we may be well assured that the various questions connected with it will be ably discussed by him.

The results comprehended in this and the previous communication are briefly summed up as follows:—

1st. That currents of electricity are at all times moving in definite directions in the earth.

2nd. That their direction is not determined by local causes.

3rd. That there is no apparent difference, except in degree, between the currents collected in times of great magnetic disturbance and those collected during the ordinary calm periods.

4th. That the prevailing directions of earth-currents, or the currents of most frequent occurrence, are approximately N.E. and S.W. respectively.

5th. That there is no marked difference in frequency, duration, or value between the N.E. and the S.W. currents.

6th. That (at least during calm periods) there are definite currents of less frequency from some place in the S.E. and N.W. quadrants respectively.

7th. That the direction of a current in one part of a plane on the earth's surface (at least as far as the S.E. district of England is concerned) coincides with the direction in another part of the plane; and if the direction changes in one part, it changes in all parts of the plane.

8th. That the relation in value between currents in a given part of the plane and currents in another given part is not constant, but is influenced by local meteorological conditions, and varies from time to time.

9th. That the value of the current of a given length, moving in a given line of direction, is not necessarily the same as of a current of the same length on the same line of direction produced, and that their relative value depends on the physical character of the earth interposed between the respective points of observation, and is tolerably constant.

10th. That the currents which have formed the basis of these investigations are derived currents from true and proper earth-currents, and neither in whole nor in any appreciable part have been collected from the atmosphere, nor are due either in whole or in any appreciable part to polarization imparted to earth-plates by the previous passage of earth-currents, or of powerful telegraphic currents; nor are they due to any electro-motive force in the earth-plates themselves.

11th. That the earth-currents in question (at least the powerful currents present at all times of great magnetic disturbance) exercise a *direct* action upon magnetometers, just as artificial currents confined to a wire exercise a direct action upon a magnet.

One of our poets, who has been rather slack of work lately, and whose eye has been rolling in a frenzy, to very little purpose, for the last fortnight, has furnished us with an idea on the subject of submarine telegraphy. He says, "it is like using the lightning conductor for a steel pen, and the ocean for an inkstand." He might have added, that the cliffs furnish the blotting-pad, the shore supplies the sand, and the whole world the sheet of paper to write upon.—*Punch.*

MR. G. G. NEWMAN'S METHOD FOR ASCERTAINING THE VELOCITY OF THE FLIGHT OF PROJECTILES.

The initial velocity of a projectile is the velocity at which it leaves the mouth of the gun. In experimenting with Mr. James Mackay's new gun at Crosby, near Liverpool, it was determined to find the time of flight from the gun to a point 120 feet in advance. Upon a first impression it will, no doubt, appear a difficult matter to accomplish this; but by a very simple contrivance Mr. Newman was enabled to obtain very accurate results. The apparatus employed is—

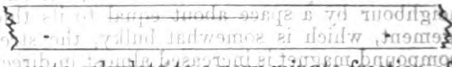
1st. A Bain's printing-machine, constructed to run rapidly, and with the train of clockwork carefully made, so as to ensure, as near as possible, an uniform quantity of prepared paper being passed in a given time. From eight to twelve inches of paper per second can be turned off, according to the speed at which the instrument is regulated to work. The "clip" carries two needles or pens insulated from each other, and pressing upon the prepared paper in the usual way.

2nd. A clock having a half-seconds pendulum, with an arrangement of battery contact springs to send momentary currents.

3rd. Batteries and gutta-percha wire as required.

The *modus operandi* is as follows:—The clock is placed in circuit with one of the insulated pens, so that at each beat of the pendulum a mark is put upon the prepared paper, showing the length paid off in each half second. The other pen indicates the time of flight, and is brought into use thus:—

A copper wire of 24 or 30 gauge is carried across the muzzle of the cannon, and passed backwards and forwards two or three times, so that it is certain to be ruptured. In the line of range, and 120 feet from the gun, two poles are erected, and copper wire, as before, stretched across zig-zag, so that there can be no possibility of the shot missing it. It will be seen, that whilst the wire across the mouth of the gun remains intact, the battery is upon short circuit; but immediately the gun is discharged the wire is broken, and the current then traverses the longer circuit, flowing through the crossing wires at 120 feet from the gun, and by the return wire to the insulated pen, marking a line upon the paper, which it continues to do until the shot, in its course, breaks the second wire stretched across its track. It will be obvious, therefore, that a diagram is obtained on the paper similar to this:—



which it is easy to calculate to a very minute fraction of a second.

By this method several advantages are gained—1st. Simplicity of action; 2nd. The instrument is self-registering; and 3rd. No time is lost by putting into operation, by the aid of electro-magnets or otherwise, any complicated mechanism.

THE INTERNATIONAL EXHIBITION, 1862.

(*Continued from page 153.*)

8. *Step-by-step Letter-showing and Printing Instruments.*

(*a.*) *Letter-showing Instruments worked by Magneto-electric Currents.*—The dial, or step-by-step index, and printing instruments will next be described. The system of transmission on which they are founded differs essentially from that of the foregoing codes, inasmuch as the step-by-step instruments directly communicate the words, spelt in the usual letters; each of which, instead of being produced by a certain constant group or succession of currents, requires as many shocks or currents for its production as there are letters on the dial following that by which it was preceded. Several excellent instruments of this class were shown, which were worked by magneto-electric currents. They have all much in common, and are merely modifications of the first form invented by Professor Wheatstone in 1840.

The receiving apparatus in all cases consists of a step-by-step propelment, worked from an electro-magnet by alternate or reverse currents, and carrying a light index round a dial marked with the letters of the alphabet, accompanied sometimes by other symbols; each current moves the index forward one letter, and the index is moved from any given letter to any other by simply sending the required number of currents.

The transmitting apparatus in almost every case consists of an axial arm moved round a dial corresponding to the dial of the re-

ceiver, and so connected by gearing with the coils or armature of a magneto-electric system as to send one current through the line for every letter passed by the axial arm. These currents are alternately positive and negative. As all the instruments of this kind exhibited have so much in common, they will not here be described in all their details, but the peculiarities of each will be mentioned.

The points to be aimed at in instruments of this class are—first, to produce powerful and equal currents in the transmitter, depending for their intensity as little as possible on the skill of the operator; and, secondly, to construct for the receiver a very light and sensitive propelment which can be worked at high speeds by weak currents without risk of losing a step from sluggishness, or of allowing the index to overshoot the mark when the signals cease, as will frequently be the case with defective escapements, owing to the momentum of the moving parts.

In this class of instruments, as in all dial instruments, there are several serious difficulties to be overcome. The correct transmission of each letter depends on the correct reception of the foregoing letter, so that one error in the reception throws all the subsequent letters wrong, and necessarily entails an interruption and repetition of the message, whereas in the usual symbolic codes, such as the Morse, each signal is absolutely self-dependent, and the loss of a dot or dash is frequently of little or no consequence. The number of currents required for each signal is so large as greatly to increase the chance of failure in each signal.

On the other hand, any person who can read or write can, with these instruments, send and receive signals. No battery is required, and the instruments are, therefore, always ready for use. These great advantages have procured their extensive adoption for private and railway lines, police or fire stations, &c., especially in England and Germany. It may also be said that the difficulties described have been successfully overcome by the admirable workmanship and design of several of the instruments exhibited.

Siemens, Halske, & Co., M. (United Kingdom, 2,959), exhibit a simple and powerful magneto-electric dial instrument. In the transmitter the induction coil is wound longitudinally on a long soft-iron bar of an H section, the coils are protected outside by two brass strips, and the outer surface of alternate brass and iron is then turned so as to form a long compound cylinder. This cylinder is placed vertically between the poles of a set of ten flat horseshoe magnets laid horizontally one above the other, but each separated from its neighbour by a space about equal to its thickness. By this arrangement, which is somewhat bulky, the strength of the resulting compound magnet is increased almost in direct proportion to the number of plates added.

A toothed wheel on the axis of the radial sending arm, which is worked by hand direct, gears into a pinion on the axis of the cylinder, and causes it to make one semi-revolution for every letter on the sending dial. One end of the coil is in connection with the axis of the cylinder, and thence with earth, the other end by an insulated collar and friction-spring is connected with the line. It will be seen that in two positions the soft-iron bar must act as an armature common to all the magnets, but the opposite sides of the bar will be alternately opposite the north and south poles as the cylinder turns round. The magnetism in the bar will, therefore, be reversed at each half turn, and will induce a current in the surrounding coils; it should be remembered that the bar is not magnetized longitudinally, but transversely, and that the coils are wound up one side, and down the other side of the cylinder parallel to its axis. Each current is produced by a double action in the long armature, first, by the loss of polarity, consequent on its leaving the poles of the magnets; and, secondly, by the gain of the opposite polarity on its approach to the poles in a reversed position.*

If, however, the operator turns too quickly or too slowly, the currents will diminish in strength; in this and all similar instruments the danger is, that the operator will move the handle or axial arm too slowly both at starting and stopping. To remedy this, the letter-dial of the transmitter is surrounded by a metal ring with as many incisions or notches as there are divisions in the letter circle; the handle of the transmitter when stopped rests in one of these, and when turned must be slightly raised. These notches enable the operator to stop the handle by allowing it to fall sharply into the notch opposite the required letter. This device permits the operator to move his handle at full speed till the last current is sent, but nothing except practice will enable him to start at full speed—a necessary condition for accurate sending. Messrs. Siemens recommend 120 turns per minute as the proper speed for the sending arm.*

Any backward motion of the sending arm or coil cylinder would send currents in the very same manner as the forward motion, but the receiving index would move forward although the sending arm went back. It is, therefore, desirable to prevent all chance of such a backward motion, either from accident or want of skill on the part of the operator. This is very effectually done in Messrs. Siemens' instruments by three short levers hinged to the frame round the cylinder on pins parallel to its axis. When the cylinder turns in the right direction they rest lightly on the surface of the cylinder, held in that position by spiral springs. But these levers are just so long that, if the cylinder be turned the wrong way, they become jammed between its surface and their own hinges, stopping all further motion in the wrong direction.

The propelment of the receiving instrument is driven from an armature arranged as in Messrs. Siemens' polarized relay. This armature carries a fork, the two branches of which are of equal length; the axis of the index, bearing a small ratchet with thirteen teeth, lies between the branches of this fork. Two flexible spring pallets, one pressing against the top and the other against the bottom of this ratchet-wheel, are fixed to the two branches of the fork; these pallets work the propelment, as the fork is moved to and fro by the armature. Two screws adjust the play of the fork, and two other adjusting screws are placed at the back of the two spring pallets. Their function is very important; they are so adjusted that the spring cannot rise up so as to allow one or more teeth to pass until the pallet itself is moved a little forward; by this arrangement one pallet acts as a dead stop to the ratchet-wheel when the other pallet has just taken a tooth. With this escapement in proper adjustment it is absolutely impossible that the index should fly round or slip a tooth; it can only fail by want of strength in the received current to work the armature. The pressure of the spring on the inclined surfaces of the ratchet teeth adds, however, a little to the friction.

This instrument was tested with a resistance equal to that of 468 statute miles of No. 8 iron wire in circuit, and found to work perfectly. Similar instruments have for years been worked direct through a line of this length between St. Petersburg and Moscow. They have also been used for seven years in Bavaria for railway purposes, where there are usually six instruments in circuit, with the end stations twenty-five miles apart. Each instrument has a sending and receiving dial. When receiving, the currents do not pass through the induction coils; but in sending, the currents pass through the home dial, and show the operator that his signals are transmitted. There is a provision for making a home circuit to test the instrument, and also for setting the receiving dial to zero, or, as it is usually called, to the cross.

The transmitting arrangement is very powerful, and the receiver extremely good in design and execution, but both parts are far larger and heavier than the specimens exhibited by other English makers, and have consequently a somewhat clumsy appearance. The plan of starting and stopping the radial arm by hand for each successive letter is inferior to the continuous motions adopted by Professor Wheatstone, and subsequently by Mr. Wilde, but Messrs. Siemens consider their transmitting coils to be so powerful as entirely to obviate all danger from unequal speed in their revolution. They justly claim great simplicity and strength of construction, and state that above 700 of these instruments have been successfully at work for periods of from five to seven years.

W. T. Henley, H.M. (United Kingdom, 2,908), exhibits a magneto-electric dial instrument, in which the transmitting arrangement is novel. In this instrument the coils and permanent magnet are fixed, and the permanent magnet is never left without an armature extending between its two poles, although some portions of the armature are continually changed. The induction coils are wound on a soft-iron horseshoe, which is placed with its two poles in a vertical plane between two poles of a deep, powerful horseshoe magnet, lying in a horizontal plane. The polarity of the soft-iron horseshoe is reversed, and the required current induced, by connecting the poles of the soft-iron horseshoe alternately with the one and the other pole of the permanent magnet, by small soft-iron armatures. These armatures are placed in two parallel horizontal rings, the peripheries of which are on a level with the poles of the soft-iron horseshoe. There are thirteen armature pieces in each

* The alternate reverse currents induced by each half turn will, at a constant speed, be perfectly equal, for they are each produced by an exactly similar action.

* This does not mean that 120 letters per minute are to be sent.

ring, each separated by an air space, and the spaces of one ring are over the centres of the armatures of the other ring. The armatures are fastened on a brass wheel, and as this is turned round they pass in front of the poles of the permanent and temporary magnets, and make the following junctions in succession:—First, one of, say, the upper armatures connects the upper soft-iron pole with the permanent north pole, and one of the lower ring of armatures connects the lower soft-iron pole with the permanent south pole.

In this position two short armatures and the long soft-iron horseshoe, which has then its maximum polarity, form a nearly unbroken long armature, joining the two poles of the permanent magnet; as the brass wheel is turned the upper armature advances over the soft-iron pole, and the lower one recedes from it, until the upper armature forms a complete bridge between the two poles of the permanent magnet; while, on the other hand, a space between two armatures is opposite the lower soft-iron pole; in this position the soft-iron horseshoe has no polarity. As the motion continues the lower soft-iron pole is connected by a new armature piece with the permanent north pole, while the original upper armature piece passes over, so as to connect the upper soft-iron pole with the permanent south pole, and in this position the soft-iron horseshoe has a maximum polarity opposed to that produced by the first combination; the cycle is completed by the lower armature's forming a junction between the two permanent poles, leaving the soft-iron horseshoe again without polarity. During this sequence two opposite but equal currents are induced in the coils, and, nevertheless, the permanent magnet is always provided with a direct or indirect armature. The radial sending arm or handle is simply fixed on the brass wheel, so that no gearing is required.

The advantage claimed for this arrangement is that the permanent magnets retain their magnetism much longer than when the armature is torn away each time a current is induced. It may be said, on the other hand, that other arrangements—such, for instance, as that of Messrs. Siemens—have been in use for seven years at least, without any notable change in the magnetism of the permanent magnets.

Mr. Henley's instrument is moved direct by hand, but there is no notched wheel to enable the operator to stop suddenly, and no contrivance to prevent the handle from being moved back—it is consequently somewhat liable to fail in unskilful hands. There is a convenient arrangement by which either the line and home receiver, or the line alone, can be put out of circuit, for the purpose of regulating the agreement between the indicating and sending dials. In the receiving instrument the armature of the receiving electro-magnet is arranged as in Mr. Henley's other well-known instruments, and works a ratchet-wheel with twenty-six teeth by means of a fork. The writer is of opinion that it is just possible in one position of the fork for the index to turn without any corresponding motion of the armature.

A pair of these instruments worked correctly with a resistance equal to 185 miles of No. 8 iron wire in circuit.

(To be continued.)

THE PRACTICAL DEVELOPMENT OF THE SCIENCE OF ELECTRICITY.

On Monday, the 7th ult., an excellent paper was read to the members of the Galway Protestant Mutual Improvement Society, by Mr. Weir, telegraph clerk, on the above subject. The essayist illustrated his discourse by experiments, having a plate-glass electrical machine and Leyden jar, an electro-magnetic coil machine, and a magnetic electric machine in the room.

Mr. Weir commenced his essay by remarking that he had chosen the subject of electricity because of his practical acquaintance with it. Although parties entering the service of the Telegraph Company were not necessarily required to have a knowledge of the science, still it was to the advantage of the operator to be thoroughly conversant with the instruments in use, and the causes which led to such wonderful results. The most eminent electricians hesitated to give a decided opinion on the nature of the agent by which the phenomena termed electrical are produced. It has been considered probable that the effects to which have been given the names of heat, light, electricity, and magnetism result from the same agency in different conditions. Of the universality of electricity Professor Faraday states that there is as much employed to combine the gases in one drop of water, as would, if instantaneously liberated, cause a flash of lightning sufficient to rend the majestic oak, or destroy animal life. Electricity remains balanced and quiescent in bodies still excited, and some substances evince electrical properties more readily than others. About 1729 an important discovery, that of electrical conduction, was made by a Mr. Grey, of the Charter House, London. In attempting to render metallic substances attractive by friction, he found that although these substances were not excitable in the ordinary way, yet they might acquire an attractive power by placing them in communication with an electrified body. He found the attractive force capable of being conducted through metallic wire, but when cords of silk were substituted, the electric action disappeared. It was thus found that certain substances had the power of confining the communicated electricity upon other bodies, in which it could not, under the same circumstances, be so excited, while the non-electric substances allowed the electricity to pass off. Hence arose a distinct series of phenomena, dependent on what has since been termed electrical conduction, giving origin to a new classification of substances considered conductors of electricity.

In 1733, Du Hay, a French philosopher, discovered the existence of two kinds of electrical power, attraction and repulsion. Two equal and opposite powers are called into play, while these actions, when combined, condense or saturate each other, and thus neutralise the free action of either. Late experiments prove that the electric fluid is material, and is influenced to a certain extent by the laws of gravitation. There is another form of electrical charge, depending on the influence of excited bodies upon neutral conducting bodies, termed "electrical induction." Induction appears to be essential to the phenomena both of attraction and repulsion, and is attendant on both, perhaps preceding them. But neither attraction, nor change, has any dependance whatever on the solid contents of conducting bodies. In order to excite and collect sufficient electricity, electrical machines have been used. These instruments require an electric or substance capable of excitement; an exciting substance or rubber; and an insulated conductor, to receive and retain the electricity. We are said to be indebted to Otto Guericke, a burgomaster of Magdeburg, for the first idea of an instrument of this kind. Having mounted a globe of brimstone on an axis, he caused it to revolve against his hand and thereby obtained a rapid and powerful excitation. Various alterations have taken place, until the machines now in use were resolved on, in which the electric to be excited is either a hollow cylinder or a circular plate of glass. Positive electricity is generally obtained from the electric, and negative from the rubber. When we require positive alone, the conductor attached to the rubber for receiving the negative electricity is connected by a wire to the earth, and the negative is thus carried away. Conversely, when we require negative the positive conductor is connected with the earth, so that either electricity can be obtained at will. The lecturer then gave a lucid description of magneto-electricity, the essential principle of which consists in the converse operation of magnets, either permanent or temporarily produced, in the common electricity of non-magnetic bodies. The essayist then referred to the discoveries of Franklin, and mentioned the circumstance of Professor Richman, of St. Petersburg, losing his life while following up the successes of Franklin. In August, 1853, having erected an insulated rod from the top of his house and attached to it an electrometer, he stooped during a thunder-storm to examine the index, when a large globe of blueish fire struck him on the head, and he instantly expired. By experiments it has been found that the electricity of the atmosphere has a daily ebbing and flowing period, like the sea, being found to increase and decrease twice in the twenty-four hours. The first practical result of Franklin's discoveries was the lightning conductor. Sir Snow Harris improved upon it, and as an instance of the value of this invention it may be mentioned, that the Navy lost from £6,000 to £10,000 in property annually, and about 300 seamen by lightning; but since the system of lightning-conductors has been fully carried out, damage by lightning has entirely vanished from the records of the Navy. The difficulties which prevented the production of continuous electric light have very nearly been overcome. Its intensity seems eminently qualified for light-houses, railway signals, &c., and it will, ere long, supersede gas, oil, &c., for these purposes.

But perhaps the most wonderful application of electricity to the purposes of life is the facility it gives to persons separated by hundreds of miles to hold instant communication with each other, annihilating space as it were. The action of the electric telegraph is based upon the simple principle discovered by Professor Oersted, of Copenhagen, in 1819, that a magnetic needle, free to rotate about its centre, when brought near to a wire through which an electric current is passing, tends to place itself at right angles to that wire, the direction of its motion following a certain law; and secondly, that a piece of soft iron is rendered magnetic during the transmission of an electric current along a wire coiled spirally round it. A current, however, passed through a single wire, would not thus act upon a needle from a battery at any great distance, hence a large coil of wire is passed round each needle, and the consequence is that the power of the action is multiplied in proportion to the number of turns made. Professor Wheatstone and Mr. Cooke took out a patent together in 1837, for applying this discovery to the instrument that first sent intelligence from place to place with the speed of the lightning's flash. In 1846 Mr. Henley took out a patent for a magnetic electric apparatus, its action as a telegraph instrument being much the same as the electric telegraph, but the electricity is derived from magnetism, and the number of movements of the needle, which represent the letters of the alphabet, different. There are now numerous forms of instruments used in telegraphy, and numerous companies competing with each other. The needle instruments have, within the last few years, given way to others of more efficiency, such as the bell instrument, invented by Sir Charles Bright; the registering instrument by Morse, which marks the

characters representing the alphabet on a slip of paper; the typo-telegraph by Hughes, which actually prints the message; and the latest by Casselli, an Italian, by which the message transmitted and delivered will be a fac-simile of that written by the sender. But this system is not very general yet, and it is feared will not be very successful. The invention of the telegraph has been a source of employment from electrician, manufacturer, and contractor, down to the humblest labourer.

The paper was listened to with the utmost attention, and at the close, when Mr. Weir offered to give any of the members a "shock," much merriment was created when several of those present joined hands, and forming themselves into a ring, availed themselves of his kind offer. A powerful battery having been got into order, several were involuntary brought to their knees, lustily calling out *peccavi*, as they were completely at the mercy of the operator, being incapable of freeing themselves.

ATLANTIC TELEGRAPH COMPANY.

An extraordinary general meeting of the shareholders in the above company was held at the London Tavern, Bishopsgate-street, on Thursday last, for the purpose of receiving the report of the directors on a contract for manufacturing and laying the cable in the summer of 1865; for authorising, under the powers of the company's act of parliament, an increase of the company's unguaranteed capital, by the issue of new capital, to an amount not exceeding £150,000; to authorise or otherwise, as provided by the "Atlantic Telegraph Amendment Act, 1859," the issue from time to time, of bonds or mortgages for such amounts, as to the directors may seem expedient, not exceeding, on the whole, the sum of £100,000; and to do or perform any other thing which might be found expedient for carrying out the foregoing arrangements. The chairman of the company, the Right Hon. James Stuart Wortley, presided on the occasion, and was supported by a large attendance of the board of directors, as well as there being a large number of the proprietary present.

The SECRETARY having read the notice calling the meeting,

The CHAIRMAN proceeded to say that on the occasion of their last meeting, on the 16th inst., in answer to the appeal of the directors to the proprietors, for their confidence, they very kindly consented to an adjournment till that day, when he (the chairman) ventured to suppose that they should not have a less attendance on the present occasion than on the former, and he also told them that as they placed confidence in the board, they should be able, on the present occasion, to give them information of a most interesting character, in regard to the great work in which they were engaged. Since their last meeting, their progress had been such that they could not yet give all the information promised, and therefore premising that they did not give all that some of them might wish, he must still further appeal for a continuation of their confidence, in the mean time assuring them that they had considered every point in the contract which they had made, with a view to the interests of the general body of the proprietary. There were reasons which might prevent his giving all the details of the contract, but the amount of information which he should be able to present to them, would prove that the directors had not been negligent of the interests of the shareholders, but had done their best to conduct their business to a successful issue. He might say that this was the first of two great epochs in connection with their great enterprise, he might call it the laying of the first stone, and as such they had now but to ask their sanction to the contract for laying the cable. The next great epoch would be when, in about fifteen months hence, they should meet to celebrate its successful submersion. Since last they met, the documents to which he then referred, as being in the hands of the lawyers, had been completed, and he had now to inform them that they had contracted with the eminent firm of Glass, Elliot & Co. for the manufacture and laying of the cable. They were the persons whose cable was chosen by the eminent scientific committee to whom they had referred the choice of the cable best suited for their purpose; and they were the persons who had had most success in the laying of deep-sea cables; and although they might be somewhat startled at the amount which it would cost to lay a cable across the Atlantic, yet he was glad to be able to say that those gentlemen had shown a disposttion to treat the company with honour and liberality in relation thereto. He had led them to anticipate on the last occasion of their meeting that the sum for the cable would be a large one. It was hoped at one time that that which might have been chosen would have been cheaper than the last, but he regretted to say that such was not the case. That approved of was heavier in air, but not in water; its breaking strain was much greater than the former, as well as its contract strain; but what was worse was the fact that it was more expensive, as there was additional expense on account of the bulk; an advantage was gained in the strength of the strain, which was a matter of essential importance. The price which they will have to pay for the cable from England to America (including the laying) will be £700,000. It will occur to you that the paid up capital amounts only to £316,000; but the directors had been able to make arrangements by which payments will be made as the work proceeds, and if they are successful in laying the cable, they will be in a position to earn large profits, and then a bonus will be given to the contractors in unguaranteed shares of the old company amounting to £137,000, or nearly equal to 20 per cent. on the price of the cable. £350,000 will be paid in cash, £250,000 in guaranteed 8 per cent. shares, not to be paid at once, but as the work proceeds, and £100,000 in debentures, making in the whole the £700,000 as the price of the cable; and if successfully laid, there will be the bonus of £137,000 to be supplied—not in cash, but in shares and in portions—at the completion of every thirty days, as the cable should continue in working order. He would have been very glad to have been able to state every circumstance in connection with the matter; but he would appeal to them, that if the directors, by what they had done, had hitherto commanded their confidence, that they would not press them for further information, which might prove inconvenient. He might inform them that the delays incident to the legal profession had been got over, that the draft of the contract was then in the room, that it had been approved of by the solicitors on either side, and that, though not on parchment, it might be considered complete. Under those circumstances, it became necessary for them to provide for their liabilities; they had £316,000 in cash, having increased their resources as he explained at their last meeting; but as they had undertaken to provide £350,000 in cash, it became them to appeal to the proprietors and the public to put them in funds. At one time it was very difficult to get subscribers to the capital at all, but he was very glad to say that since the last failure public confidence in the undertaking had risen far higher; he might, indeed, instance his own case, for, although not a capitalist, so great was his confidence in its ultimate success, that he had gone on purchasing shares to the present time. It was the intention of the directors to issue £50,000 in 8 per cent shares to make up the deficiency in the £350,000, and if that should fail, which they could not anticipate, they had arranged that the manufacture of the cable should not be impeded, and, although he made an earnest appeal that they would assist the directors by taking up the shares, yet they had made such arrangements as would, in any case, secure the interests of the proprietors. He believed that he had fulfilled his task. He would now conclude by urging them to recommend the undertaking to their friends, to use their influence to interest them in the noble work which they had undertaken, a work which was unparalleled as one of the wonders of science, and which would be worthy to rank side by side with the seven wonders of the world; a work which was as a giant by the side of the Colossus of Rhodes, which was merely made to stride across a narrow stream, with his foot on the land on either side, whilst this would unite the interests and he hoped the hearts of two great bodies in the Old and New Worlds, and, by doing so, cement that friendship which should ever exist between the whole of England and America, and when that terrible cloud which now hangs over that unhappy and distracted country shall clear away, he trusted that that affection would revive towards this country which ought to exist between the mother country and her offspring, and which this noble and gigantic undertaking would aid in facilitating, for it will stride across the ocean, and thus connecting the two countries, will hold out the hand of friendship from one to the other, till that time should arrive when the lion and the lamb shall lie down together. (Hear.) He would now move "That this meeting, having heard the chairman's explanation of the contract entered into, by the board, with Messrs. Glass, Elliot, & Co., for the manufacture and laying down of the company's cable, hereby signifies its approval of the same."

Mr. JEWSBURY having seconded the motion, it was put to the meeting, and carried unanimously.

The CHAIRMAN said he had now to ask the proprietors to authorize the directors to issue additional capital, so that after the completion of the contract they may be able to pay over to the contractors paid up shares to the amount of £137,140. For this purpose he would move "That under the powers of the 'Atlantic Telegraph Company Amendment Act, 1859,' the ordinary unguaranteed capital of the Atlantic Telegraph Company be, and the same is hereby increased by the creation of 6,857 new shares of £20 per share, representing a par value of £137,140; and that the directors be, and they are hereby empowered, so soon as the contractors shall have successfully completed the submersion of the cable, in accordance with their contract and specification, to issue to the said contractors in manner provided in the contract, the said shares credited in the company's books as fully paid up shares."

The motion having been seconded by Captain HAMILTON, was put to the meeting, and carried unanimously.

The CHAIRMAN said that he had to trouble them with but one more resolution, and previous to reading it, he felt that he could not but congratulate the meeting on the fact, that the contractors so far evinced their confidence in the final success of the undertaking, as to be willing to take debentures in this company to the amount of £100,000 as cash. He would now move "That the directors be, and they are hereby authorized under the powers of the 'Atlantic Telegraph Amendment Act, 1859,' to issue from time to time, under the seal of the Atlantic Telegraph Company, bonds or mortgages on the stock and property of the company in such separate amounts, and bearing such annual interest and for such terms of years as they may deem expedient, and to renew and pay off the same from time to time as to them may appear desirable; provided, that the entire amount for which the said bonds are issued shall not at any time exceed in the aggregate the sum of £100,000."

Mr. EDWARD MOON having seconded the motion, it was submitted to the meeting, and carried unanimously.

The CHAIRMAN said that the business of the meeting had now been

brought to a termination, and he had to thank the proprietors for their attendance, whilst he trusted that they would do all in their power to advance the interests of their noble undertaking.

Dr Black said that, before they separated, they had a duty to perform to the chairman and the directors. But for the bravery and intelligence which had been exercised by those gentlemen, the company would not have been in the excellent position it then was, for it had required a great deal of bravery and intelligence on their part to combat with all with which they had had to contend, and to enable them to present the meeting with such a statement as they had heard. He had, therefore, the greatest pleasure in moving, "That the most cordial thanks of this meeting be presented to the chairman and the board of directors, for the very able manner in which they had conducted the affairs of this company, and to the chairman for presiding on this occasion."

Mr. Hack seconded the resolution, which was put to the meeting and carried unanimously.

The Chairman, in reply, said that he had to return thanks on behalf of the directors and himself for the compliment they had been pleased to pay them. It was the first time that he had ever had to return thanks, not merely for presiding at a meeting, but for the course he and his colleagues had taken to carry on the affairs of the company. In thanking them for their sense of approbation, he might be allowed to say, that though he might have persevered in the cause under circumstances of great difficulty, yet he could not have done anything if he had not been assisted by such commercial men as constituted the board. Whilst it were almost invidious to mention names where all had rendered able assistance, he felt that he might notice those of their excellent vice-chairman (Captain Hamilton) and Mr. Cyrus Field, who, within the last week or ten days, had brought parties together by which they had been able to conclude some of their great affairs. In conclusion, he begged to thank them on behalf of his colleagues and himself for the mark of their approval now presented to them.

CORRESPONDENCE.

TELEGRAPHIC FAC-SIMILES.

To the Editor of the Telegraphic Journal.

Sir,—The article complained of for its inaccuracy as to date, and in other respects, by your correspondent "One who took part in the Experiments," was copied from a scientific work. The date should have been 1851, as your correspondent states. As to the other matters complained of, not being present at the experiments, I feel thankful to your correspondent for the correction. That the invention was in existence in 1848, I have only to say that Mr. Alexander Bain fully described the instrument to me long before that date, and I believe that he was the true inventor of that mode of transmission; and in 1858 he related to me the history of the invention, and the manner in which he was deprived of the credit or the advantages which might accrue therefrom.

Veritas.

FAULTS IN INSULATION.

To the Editor of the Telegraphic Journal.

Sir,—I have referred to the pages of Mr. Culley's work in which the above subject is treated, and to which the attention of your correspondent "K. H." has been directed. I confess that I cannot exactly comprehend how the effect of a fault on signals can be greater when nearest the sending station, provided the resistance of the leakage remains the same. Suppose a wire, 180 miles in length, is charged with a battery of 24 cells, which charge has to overcome a resistance at a fault within 20 miles of its distant end, equal to another twenty miles of the same wire, we should then have a resistance, exclusive of the instruments and batteries, of 200 miles against the working current, or a loss equal to the electromotive force of 26 cells of the battery. On the other hand, let the wire be charged at the end nearest the fault with the same battery-power, the loss still would not exceed the force represented by the 26 cells, unless the fault be increased by its proximity to the battery.—Yours, &c.,

John Melford.

Dublin.

PERSIAN GULF TELEGRAPH.

To the Editor of the Telegraphic Journal.

Sir,—It is now, I believe, nearly two years since I have read, in some of the papers, of an India-rubber manufactured cable having been sent by the Indian Government to the Persian Gulf. I have no recollection of having ever read of its being laid, or what has become of it. As I have great confidence in the applicability of india-rubber for submarine telegraph purposes, I should be exceedingly glad to learn something about the said cable, and with that view, I must ask you kindly to insert this letter, hoping that it will elicit the required information from one of your Indian subscribers.—I remain, &c.,

P. Waithman.

TELEGRAPHIC NEWS.

Mr. S. Statham.—We deeply regret to have to announce the demise, in the fifty-ninth year of his age, of the above much respected gentleman, for many years the manager of the Gutta Percha Company, Wharf-road, City-road. Mr. Statham had been suffering some time from severe illness. We believe that it was Mr. Statham who first suggested gutta percha as an insulator for subterranean and submarine telegraph wires. The first wire was covered for Mr. Ricardo, we believe, in 1845, upon which we had an opportunity of making several electrical experiments at the time.

Telegraph Clerks' Provident Fund.—In our last it was stated that the British and Irish Magnetic Telegraph Company had given a donation of £15 15s., and that the Messrs Rothschild had subscribed £10 10s to the above fund. The esteemed secretary desires us to correct the foregoing announcement, and to state that the British and Irish Magnetic Company will allow *an annual subscription* of £15 15s., and that Baron L. de Rothschild has given *a donation* of £10 to the fund.

Electric and International Telegraph Company.—The Lowestoft cable laid in 1862, and which had been out of repair during the winter, was successfully repaired on Monday, the 28th ult., by Mr. C. Varley, electrician, and Mr. J. Blacklock, submarine engineer, of the company. The fault was found to be in 30 to 32 fathoms, and the repair was executed during a very severe storm.

Telegraphy in the Isthmus of Suez.—The whole route of the Isthmus of Suez has been placed in communication by the telegraph. The principal stations are Port-Saïd and Suez, the two extremities, and Ismailia, the centre. Thence the wires pass Tell-el-Kebin and joining Zagazig, which city is in communication with all Egypt, and consequently with Alexandria, correspondence may be carried on with all the European capitals.

Gisborne's Electric Steering Apparatus.—We have on more than one occasion referred to this extremely ingenious and efficient contrivance. Its employment on board Her Majesty's iron-clad frigate Royal Oak is thus described by the commander, in a letter to the patentee:—"Corfu, March 12, 1864.—Sir,—With regard to your 'Electric Steering Signals', I cannot say enough in their favour. In foggy weather, and at night time, they are *most valuable*, especially when in the midst of shipping, or bringing up in a crowded anchorage, when it is necessary to conn the ship from as far forward as possible. Your signals being placed on the fore-bridge, one is nearer the object in view, and directions can be given the helmsman instantaneously, and without hailing, or chance of misinterpretation. Knowing their value I should be very sorry to be without them, and I do hope they will be universally adopted throughout the navy."

Sale of the Brett Collection.—The late Mr. J. W. Brett, who was designated by Professor Morse, "the father of submarine telegraphy," was also an artist of considerable attainments, besides being a man of varied and refined taste, united with that indefatigable enthusiasm of research without which the collector, however fortified by wealth, fails to realise such comprehensive dream of rare possessions. Taken as a whole, the assemblage of pictures and other objects of art, privately exhibited during the past few days, at the residence in Hanover-square, is one of the best representative gatherings recently brought under an auctioneer's hammer. The sale, at Messrs. Christie and Mansons, will commence on the 5th instant, and will extend over ten days, previously to which the collection will again be on view for a short period. Several of the paintings are well known, as, for instance, the noble "Entombment," painted by Titian for Philip the Second; the portrait of a little Spanish girl, by Velasquez; the "Adoration of the Magi," which, when in possession of the late Lord Northwick, was attributed to Van Eyck, but which is now, with greater likelihood, assumed to be the work of Hemmelinck; and the fine "Boar Hunt," by Rubens and Snyders, a picture which would be a valuable addition to our national art-treasures, so deficient in examples of the last-named painter, albeit undoubtedly rich in the labours of the great Peter Paul. It would be impossible within our present limits to enumerate all the works worthy notice in this collection, ranging, as they do, over the widest fields of art, and including productions of every known hand, from Fra Angelico to Vandyke, and from Raffaelle to Greuze. We cannot, however, pass some of the most salient features without expressed recognition. There is a remarkable tempera painting, by Raffaelle, from Cardinal Rossi's collection, representing "Christ bearing the Cross," and so marvellously fresh in the light colours, which give it a peculiar effect of space, as to suggest a modern resemblance to the works of the late Mr. Dyce. Curiously enough, there is, in an adjoining room, one of this lamented painter's happiest efforts, a "Virgin and Child," which might, on its part, recall the spirit and manner of Raffaelle. The collection is notably rich in the richest of Stothard's works; and it boasts many fine examples of the great Sir Joshua, characterised by his utmost grace of expression. Among the drawings are some of Mr. Brett's own execution, showing much versatility, without loss of power in the changes of style and subject. The miscellaneous articles of the collection comprise a large array of carvings, bronzes, porcelain, Limoges enamels, goldsmith's work from the sixteenth century downwards, gems, engravings, medals, and coins. Careful and effective photographs of the principal objects have been taken by Mr. Ayling, of Oxford-street, and from his pictures an illustrated catalogue has been prepared.

The Electric and International Dramatic Club.—This society gave a benefit performance at the Cabinet Theatre, King's-cross, on March 16th. The pieces selected for the occasion were "Raising the Wind," "Furnished Apartments," and "Love in Humble Life," interspersed with an Ethiopian entertainment, and the talented performance of Master Montague, the "Infant Nonpareil." In "Raising the Wind" the character of "Sam" was sustained by Mr. James Cook with his usual marked ability, and obtained for him hearty applause; nor must we omit to notice the very able manner in which Mr. Garrard played the arduous part of "Jeremy Diddler." Messrs. John Young, Tripe, and Gilbert, most effectively supported the various *rôles* entrusted to their representation, while the minor parts were played with commendable care by Messrs. Simmonds, Hester, and Barker. This piece was a decided success, and highly relished by the audience. In "Furnished Apartments" Messrs. Garrard and Tripe acquitted themselves with their wonted ability, whilst Messrs. Boxall, Brandon, and Simmonds also performed their parts to general satisfaction. The Ethiopian entertainment caused much merriment. It must be stated that these gentlemen came forward at the eleventh hour to assist in the work of charity and goodwill, and the necessarily few rehearsals would amply excuse any slight hitches that were apparent. We cannot, however, omit to record the due meed of praise to Messrs. Bright, Crawley, and Atkins. The concluding drama, "Love in Humble Life," was the crowning piece of the evening. Mr. Perry, as "Rouslaus," the soldier, was very effective, and Mr. James Cook, as "Carlitz," was especially worthy of notice, exhibiting, as he did, a most judicious and admirable combination of humour and pathos; and now, *place aux dames*, the artistic and pleasing manner of Miss H. Gower, as "Christine," added in no small degree to the beauty and success of the piece. The theatre was crowded by a select and attentive audience. We are glad to be able to announce that the performance realised a handsome sum for the gentleman for whose benefit it was given, he being one of the club's most active members, and who has been laid up for some weeks with a severe and distressing illness. We understand that the club intends giving its usual quarterly entertainment shortly.—Mr. R. Boxall, an old and valued member of the club, has succeeded Mr. J. Young, who, on his retirement as secretary, received a cordial vote of thanks for past services, and a special invitation to continue in active membership, which request was acceded to.

Galvanization of Iron.—The Society for the Encouragement of Art in France has given a prize of 10,000f. to M. Sorel, the inventor of the process for galvanising iron.

Communication with Italy.—The telegraph has been established, and is now in operation, between Lyons and Turin, by Mount Geneva. One of the advantages of this new line of communication has been a reduction from one franc to fifty cents. for messages.

The Levant Submarine Telegraph Company.—It is on record that some of our most important submarine lines have been impaired, or completely destroyed by lightning. Numerous contrivances have been suggested for the protection of submarine cables from the effects of lightning, hence we have great pleasure in inserting the following important testimony to the efficiency of a lightning-conductor supplied to the above company by Messrs. Siemens, Halske & Co.:—"Chibs Station, Nov. 20, 1863.—Gentlemen,—It is with great pleasure I inform you that, owing to your excellent plate lightning conductors, the cables belonging to this company have for the third time been saved from destruction. A few days ago a heavy thunderstorm passed over the island of Metelin, destroying eight poles completely, and the electric fluid of which passed along the line-wire into the cable-box, where it was luckily arrested from entering into the cable by fusion which had taken place between the upper and lower plates; the latter was well connected to earth. I had some difficulty to separate them. Twice before the cables landed in the Bay of Scala Nova were saved by the same means. Should you think fit to make use of this statement you are welcome to it, and believe me, gentlemen, yours very truly, W. Buffles, Electrician and General Manager."

The Bombay Line of Telegraph.—The *Ceylon Times* thus refers to the casualties which are continually befalling this telegraph:—"We wonder when the Indian telegraph authorities will turn their serious attention to the frequent interruptions on the Bombay line. Into such a chronic state of disorder have matters fallen along that line of wire that the arrival at Galle of the steamer from China is an unfailing signal for an interruption to telegraphic communication. One message goes through well enough, but the second invariably halts at some intermediate station on the southern continent, generally for a week at a time, until, in fact, the opium speculators concerned in the trick have 'made their game.' It is at all times an ungracious, and often a reprehensible act, to impute motives, but in the present case we are spared the unwelcome task. It might, indeed, be a somewhat dangerous pastime for an editor to indulge in, to charge the servants of the Indian Telegraph Department with corrupt practices. We might not escape so cheaply as a judge who taxes a jury with a similar 'itching of the palm.' But in the case under notice there is no occasion to seek for any motive whatever. The practices of certain parties along that line have been so completely unmasked, and punished by a Bombay magistrate, that the recurrence of these tricks only serves to show that there must be enormous profits made through them—sufficiently so to induce heavy temptation being cast in the way of underpaid native officials. Surely it is worth while for the chief of the department to see to this; the annoyance and loss to the commercial public are more than that functionary can well imagine."

Jersey and Piron Telegraph Cable.—This submarine line, which has been out of repair since November, 1863, was put into working condition in January last.

Merit Rewarded.—By a decree of the 5th of January, M. Ceillier, superintendent of the telegraph service in the province of Constantine, France, was named "Chevalier de la Legion d'Honneur."

Atlantic Telegraph Company.—The tender of Messrs. Glass, Elliot, & Co., to manufacture and submerge the new Atlantic cable for £700,000, has been accepted, and the work now in progress will be proceeded with under able superintendence.

The Indo-European Telegraph.—The following particulars of the laying of this important line of communication are contained in the *Times of India*, of the 29th February:—"The latest news we have from the Gulf are to the 6th February, on which day the Semiramis left for Bombay with the Kirkham in tow, all the submarine cable which the latter vessel brought out from England having been laid down along the Mekran coast, from Ras Guadur westward towards the entrance of the Persian Gulf. Perhaps many of our readers may not be aware that since April last Guadur has been in telegraphic communication with Kurrachee, through a land line of about two hundred and fifty miles. Guadur is a small fishing town on the southern shore of Beloochistan, which is known as the Mekran coast. At one time it was intended to carry a land line all along the Mekran coast, but various considerations have determined Government on preferring submarine communication, which at present will begin at the extremity of the land line at Guadur. Guadur, therefore, was the appointed rendezvous for the vessels containing the cable and the engineering and electrical staff. By the 30th ult. they were all collected there, the Bombay marine steamers Coromandel, Zenobia, Semiramis, Victoria, and Clyde, and the sailing ships Kirkham and Marian Moore. The Coromandel's duty was to act as pioneer to the vessel paying out the cable, by taking soundings, and so keeping her as much as possible in a uniform depth of water; the Zenobia towed the Kirkham, on board of which was the first section of the cable, and the Semiramis brought on the Marian Moore, with the second section. The Victoria assists in the pioneering, and is ready as an auxiliary towing power, in case of any accident to either of the others. The gunboat Clyde, by her light draught of water, is well adapted for landing the cable where it is necessary to have a shore station. The first thing to be done was to land the shore end from Kirkham, at Guadur, and this was most successfully accomplished on Wednesday and Thursday, the 3rd and 4th inst. Owing to the shallow water in the western bay at Guadur, the large ship could only get within about two and a-half or three miles from the shore but the gunboat could go much further in, and when the water became too shallow even for her, the large paddle-box boats of the Zenobia could convey the end of the cable up to the beach. Accordingly as much cable as was required to reach from the anchorage of the Kirkham to the nearest point to the shore at which the gunboat could anchor was coiled down on the gunboat's deck, the portion required to reach on to the telegraph buildings having been previously coiled down in the paddle-box boats. With these in tow the gunboat steamed towards the shore, paying out the cable as she went; and when all on board of her was finished the boats paid out till they reached the shore, when the end was quickly buried in a trench leading up to the offices. This done, there was direct communication between the end of the cable on board the Kirkham and the end in the Guadur office, while by the land line the connection was continued on to Kurrachee and Bombay. Of course, as soon as Colonel Stewart and Sir Charles Bright went on board the Kirkham, after completing the shore work, they proceeded to test the efficiency of the cable, and as soon as a message came from Kurrachee it was sent through to them—curious to say, it referred to a domestic occurrence of personal interest to the latter gentleman. The end of the cable having been thus safely landed, the laying down of the rest of the section to Mussendom, at the entrance of the Persian Gulf, had next to be proceeded with, and the same evening the vessels started—the Coromandel going before to show the way, and the Kirkham, in tow of the Zenobia, following at a little distance paying out the cable. This was on Thursday evening. On Saturday morning the Kirkham had paid out all she had on board, and the Marian Moore was brought up by the Semiramis to have the end of the Kirkham's section of cable spliced on to her's, after which the Semiramis took the empty Kirkham in tow, and went to Muscat for coals to bring her down to Bombay. The weather hitherto has been most propitious for the work, so that the cable has been laid at the rate of between four and five knots an hour, and without a single accident. The entire management is most excellent. Lieut.-Colonel Stewart is a marvel of energy, activity, sagacity, and a thorough scientific knowledge of all the details of the deeply important work which has been entrusted to his management. What one sees of him now makes it easy to believe how completely the wonderful regularity with which Lord Clyde's army was kept in communication with the seat of Government during the mutinies, was dependent on his personal exertions. Sir Charles Bright brings every tittle of the experience he has gained in many similar operations to bear on this, the most important of them all, and he is ably seconded by his numerous staff. None but those who have actually witnessed the operation can imagine the immense amount of labour which is required in laying down a submarine cable, especially in a part of the world where every necessary of life has to be carried to the stations at which employés are to be left."

MISCELLANEA.

Apt Phraseology.—In the Irish language the electric telegraph is called *Sgeol abada boita*, the literal translation of which is "news upon stilts."

The Atlantic Telegraph.—"But this little spark which we are now sending under the ocean—this flash of lightning which passes from shore to shore—this fire which burns there inextinguishably—may truly be considered, if it were not too sacred an expression to use, to be the bond of that love and of that charity between the two nations, of which the sacred text says, that 'many waters shall not extinguish it, and many floods shall not overwhelm it.' Yes, I have no hesitation in saying that it is time for the American eagle to let go those lightnings which it is represented as grasping in its talons, and let them drop into the ocean, and they will cross it safely and come to us, not accompanied with any manner of thunder, but spreading the words of softness and of peace. It is, therefore, a matter of great pride that this island has been chosen by Divine Providence as the means of this most happy communication—of this binding of nations and worlds in bonds which we may trust will be of irrevocable and indissoluble peace. It is no small pride for it to have seen the most splendidly successful application of the most magnificent of those gifts of science and genius which God has given for a blessing and an honour to this age; that after so many years of sorrow and of suffering, of calamities of every sort, of famine and disease, this glory should have been given as a recompense to this noble land."—*Cardinal Wiseman.*

The Smallest Magnet and Electro-Magnet.—Sir Isaac Newton possessed a steel magnet weighing only three grains, and which supported a weight of 746 grains, or nearly 250 times its own weight. This curiosity was set in a ring which the philosopher wore upon his finger. But the attractive power of this permanent magnet is small when compared with that exhibited by an electro-magnet constructed by Dr. Joule for his "Experiments Demonstrating a Limit to the Magnetizability of Iron" *Phil. Mag.*, Vol. II. No. 13). This was made of a piece of iron wire one-fourth of an inch long and one-twenty-fifth of an inch in diameter, bent into a semicircle, and wound with three turns of uninsulated copper wire one-fortieth of an inch in diameter. It weighed only half a grain, and carried in one instance 1,417 grains of iron, or 2,834 times its own weight. To his description of this wonderful little magnet, Dr. Joule adds:—"I subsequently had the pleasure of presenting Dr. Roget with a still more minute electro-magnet, which has sustained about 3,500 times its weight of iron."

Bonelli's Telegraph.—"M. Bonelli, the ingenious inventor of a first autographic telegraph, and of the electric weaving-loom—one of the marvels of human genius—has been endeavouring for some months past to introduce into France a system of electric transmission, as curious as it is rapid and economical. The dispatch is set up in printing type, and placed on a little carriage, which is made to pass beneath a comb with five teeth, which are in communication with the five aeriel wires of the line, at the extremity of which these same wires are joined to the five teeth of a second comb, under which passes a chemically prepared paper, carried along on a little carriage similar to the one at the other end on which the printing type is placed. If, under this arrangement, the electrical circuit of a battery composed of a sufficient number of elements, and distributed in a certain order, be completed, then at the same time as the first comb is passing over the printing type at the one end, the second comb at the other end will trace the dispatch on the prepared paper in beautiful Roman letters, and with so great a rapidity that it may be expected that 500 messages of 20 words each will be transmitted per hour. Scarcely were the first machines of the Chevalier Bonelli set up in a room in the office of the Central Administration, and even before any trial was made, when not we, but competent men well known to Monsieur du Moncel himself, in an article quoted by the *Presse Scientifique des Deux Mondes*, thus closes a critique more than severe:—'The telegraph of Monsieur Bonelli is then nothing more than an ingenious apparatus for a room, applicable at the most on very short and perfectly insulated lines, and most probably incapable of being worked over long lines under circumstances such as have hitherto existed.' We, on the contrary, courageously defend Monsieur Bonelli, as we defended the Abbé Caselli, whom the journal of Monsieur Barrel also attacked. Now on Sunday last we saw Bonelli's telegraph at work on the line between Paris and Boulogne, which is by no means a short one, being 272 kilometres, and which is so badly insulated that the wires are very often powerless to work the Morse instrument. Although the five wires were only at the disposal of Monsieur Bonelli for about half an hour, which was hardly a sufficient time to get them in working order, we were enabled from the first experiment to receive several dispatches perfectly printed, and with that truly incredible rapidity which constitutes the great hope of cheap telegraphy. Let Monsieur Bonelli be permitted to work the five wires between Paris and Lyons, or even from Paris to Marseilles, and his success will not be the less striking. We confine ourselves at present to these few remarks, because we intend shortly to give a complete description of this marvellous system of typo-telegraphy. Let us conclude by calling on Monsieur Barrel to retract, and to acknowledge that he has for twenty years past seen us in the foremost rank of progress, proclaiming loudly the genius of invention, sinning rather by an excess of boldness and good-will than by an excess of timidity and indifference."—*Les Mondes.*

The French National Telegraph.—The following figures show the progress in the number of messages sent and revenue from 1851 to 1862:—

Year.	No. of Messages.	Receipts. Francs.	Cents.
1851	9,014	76,722	60
1852	48,105	542,891	58
1853	142,061	1,511,901	57
1854	236,018	2,064,983	71
1855	254,532	2,487,159	21
1856	360,299	5,191,102	4
1857	413,616	3,333,695	74
1858	463,973	3,516,633	70
1859	598,701	4,022,799	78
1860	711,652	4,188,065	26
1861	903,610	4,919,737	96
1862	1,521,100	5,316,000	96

LIGHTNING DISCHARGERS.

THE evil, and frequently fatal, effects of lightning on subterranean and submarine telegraph lines have led to the introduction of various contrivances for protecting the insulating material from injury and destruction. It is strongly suspected that the absence of such precaution, or the employment of imperfect dischargers, have contributed to a far greater extent than at first supposed to mar the success of our submarine lines. In the report of the Government committee the subject is not even referred to, although several instances are given in the evidence of the injurious and fatal effects of lightning on long lines of underground and submarine telegraphs, and various methods suggested for their protection. It is known that the Malta and Corfu and the Toulon and Algiers cables were destroyed during heavy thunderstorms. In glancing over the register of signals which passed through the first Atlantic cable in 1858, we find that on the 13th of August the signals are represented as "perfect," on the 20th as "splendid," and that "first-rate signals were received at Newfoundland from Valencia on the same day." On the 21st the signals are stated to be "beautiful," on the 22nd "good," on the 25th "splendid sending." On the 26th we are informed that there was a heavy storm and lightning in Newfoundland, and that, in consequence of the lightning being so strong, the end of "the cable was put to earth for protection." During the remaining days of the cable's existence the current is reported as weak and variable, which evidently rendered it very difficult to carry on any communication. The gradual deterioration and the final collapse of the cable are results which might have been expected from its having been traversed by a flash of lightning, or by excessively strong currents. The evidence given before the Government committee on the subject is highly instructive, and deserves the most serious consideration, especially at a time when it is in contemplation to submerge several extensive lines of deep-sea telegraphs. Mr. Latimer Clark, in reply to the questions addressed to him, states:—

In shoal water there are numerous causes which need scarcely be mentioned—anchorage, and, above all things, rocks; and I may also, perhaps, speak of rust as being a very common cause of injury; but in deep water the chief injury, I should apprehend, would be from lightning, and from a phenomenon which constantly occurs in gutta-percha wires, which I believe now is confined to them. It is this that, after lengthened use, especially after great battery power has been long sent through them, a small fault will sometimes display itself without any apparent cause. That will not interfere with working at first; but, after a time, the currents will gradually enlarge the fault, and make it become so great as to stop all working. I never yet satisfactorily, to my own mind, accounted for those faults, and therefore they remain, in my mind, a sort of shadow on submarine cables. I should be very glad if any explanation of them could be given. At present, as far as I have seen, gutta-percha is liable to have these small faults, commencing in it without any very apparent cause, and gradually enlarge themselves till they stop the working. One result has been that we have had to lift cables, in shallow water, to cut out those faults, and replace them, which we have done without learning much from them, unless they have been made, as they have in very many cases, by lightning.

Have you seen any cases of injury from lightning to submarine cables?—Injuries from lightning are very frequent both in submarine cables and in underground wires, wherever they are in connexion with overground wires. I think the best remedy for this in submarine cables is to lay a considerable length of the telegraph near the shore in an iron-coated cable, and to place lightning-conductors both at the margin of the sea where the submarine cable commences, and also at the end where the land cable commences. In that way some resistance is opposed to the lightning travelling on and causing injury to those parts which are beneath the water; the large injuries will probably occur near the sea. I have also designed a peculiar lightning-conductor, which I believe to be extremely well adapted for burying in out-of-the-way exposed places.

What is the form of that lightning-conductor?—It is made by taking a slab of slate, drilling holes through it, and placing it upon a planed slab of iron; pins of brass are then thrust loosely through those holes, so as to rest on the iron; melted lead is poured over it, so as to cement the holes solid; this compound of a cake of slate, with these points passing through it and resting on the iron, is then lifted up, and a piece of ordinary silk or oiled silk is placed between the slate, the points, and the slab of iron, and there supported. The conducting wire is placed in connection with this slab with the points, so that any lightning would burst through the oiled silk, and make its exit to the earth. The whole of this apparatus is enclosed in a cast-iron box, luted in with pitch, and some quicklime is enclosed with it, so that the atmosphere is always kept dry within.

Have you tried that lightning-conductor?—Not practically, only experimentally. In its general form it corresponds with the lightning-conductor which has been used commonly for many years past, the peculiarity consisting in the method of adjusting the points and the use of quicklime.

Mr. Saward, the secretary to the Atlantic Telegraph Company, gives his experience with respect to the effect of lightning on subterranean lines as follows:—

Have you observed, while you were connected with the British Telegraph Company, any underground wires destroyed by lightning?—I have had specimens brought to me, which were said to have been injured by lightning.

Did you notice any peculiarity about those specimens to lead you to see how the lightning had struck the wires?—Not how it had struck them, but how it affected the gutta-percha.

Was it at all similar to the appearance exhibited by the specimens which have been produced?—No. The gutta-percha in the cases which I have seen was split open, but not riddled like the specimens I have seen on the table. I had never seen one affected that way by lightning until I saw it here. In those that I have seen the lightning seemed to have flashed open the gutta-percha altogether.

Mr. Cromwell F. Varley, from his lengthened experience in the supervision of the extensive lines of the Electric and International Telegraph Company, furnishes us with the most important information as contained in his evidence as to the injurious and destructive effect of lightning on the company's lines—aerial, subterranean, and submarine—which proves the vast importance of having efficient dischargers for the protection of the valuable property jeopardized by lightning, and more especially in the case of deep-sea cables, which cannot be raised and repaired when injured, as evidenced in the unsuccessful efforts made to recover the Toulon and Algiers line:—

You have doubtless observed the effects of lightning on underground and other wires—what has been the result of your observations?—Wherever underground wires are used in connection with forming part of overground circuits, they are sure to be destroyed by lightning in time. In the case of a line in which there are many wires, the lightning strikes the top wire, and then in numerous sparks strikes all the other wires. It then, to a great extent, makes its escape at the poles, splitting them, and sometimes knocking out pieces as if they had been hit by a pickaxe; at other times splintering the poles, and throwing the splinters to a distance of even 200 yards; and, generally speaking, a portion of the current traverses the line to the distant end, burning up such instruments as it meets in its way; or should it meet with a tunnel in which there is a gutta-percha covered wire used, or should the wires go underground covered with gutta-percha, it almost invariably punctures them. I cut out, two years ago, a fault from the Kilsby tunnel, in which there was a minute hole right through the gutta-percha, and through Mr. Edwin Clark's covering of tarred and sanded tape. The material was charred, and an electric connection established between the conductor and the roofing of zinc which covered the grooved boarding in which the gutta-percha line was located. That made a very bad fault; and upon removing the tape there was a hole, about the twentieth of an inch in diameter, through the gutta-percha, presenting all the appearance of having been burnt by lightning. It did not present the appearance of that piece of wire which lies upon the table. That I attribute chiefly to the fact that the wire was covered tightly round with tape, which held the gutta-percha in position to prevent it from bulging out by the explosion.

You said that you anticipated that any subterranean or submarine wire connected with a sub-aerial wire would be subject to destruction by lightning. Do you think that no arrangement can be made at the junction of the two wires, by lightning-conductors or otherwise, to prevent that destruc-

tion ?—In 1847 I made a lightning-conductor, in which the wires are brought very close together in an exhausted chamber; and upon testing those, I found that two feet of the exhausted chamber offered the same resistance as ¼-inch of atmospheric air; and yet this offered sufficient resistance not to allow a current from 400 cells of Daniell's battery to pass across the wires in the exhausted chamber, being very close, about $\frac{1}{50}$-inch apart. Consequently, you get by this means, I think, the nearest approach to a perfect lightning-conductor. Some of these lightning-conductors have been in use upon our lines; and in one case, at Rugby, owing to not anticipating the result I am about to describe, the machine was improperly constructed. Ten wires were led up into the exhausted glass through a slate tablet; these were all cemented in, and the glass was made tight by filling round it with cement, and covering over the tap that had been used for exhausting the glass with the same soft cement which had been carefully deprived of moisture. A little vacuum gauge was placed inside the glass to show that the vacuum was maintained. A heavy flash of lightning struck the wires on the Trent Valley line, and was discharged through the lightning-conductor in the Rugby office; the wires were heated by the discharge, and the heated wires melted the cement, which was violently projected inwards by the pressure of the atmosphere coating the glass and filling the vacuum gauge. None of the instruments were injured, and as far as that experience goes, which is the only experience we have had of a heavy discharge going through the instrument, it answers perfectly. In the case of a submarine cable, I should always recommend the introduction of at least three or four miles of underground wire between the cable and the land line; the discharge would be most likely to take place in it to the earth, and save the cable. This is not, however, always the case, for in sandy or rocky districts the ground is sometimes struck, and the ground being dry offers so much resistance to the discharge that the lightning bursts into the gutta-percha, and comes out again at some more distant point. As under-ground wires are sometimes destroyed by lightning, so under-ground wires connected with a cable might be destroyed by lightning; but the safest means of protecting a submarine cable is to solder a thick wire to every individual wire of the exterior covering of the cable, and to use those wires as the earth connection of your lightning-conductor, which should be a vacuum one, such as I have just described. Then if the ground itself be to a certain extent an insulator, and lightning flash into your wire, it will go to the exterior of the cable at once, because that is the best connection with the earth at that point; and having charged the exterior of the cable for a moment, which it will do at that very instant, which is the dangerous moment, the interior of the cable has no power to take in electricity, as Faraday has shown by an insulated jar, in which, when you place a charged ball, and let that ball touch the interior of the vessel, the electricity immediately escapes to the exterior; and upon taking that ball out, there is not a trace of electricity there. Therefore, the exterior metal covering of the cable is the next earth connection that can be selected for preserving the cable. I would, however, recommend that at the end of the length of underground wire of five miles, where it joins the land line, you should also have another lightning-conductor. There is then a double chance, and that is very important in submarine cables. However, should the submarine cable be destroyed by lightning, it will probably take place within a distance of fifteen or twenty miles at most, at which repairs are easily performed.

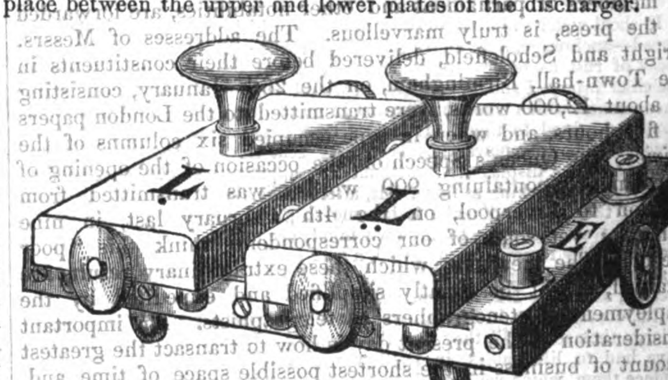
Mr. W. H. Preece, A.I.C.E., in his evidence supplies some interesting facts illustrative of the imminent danger to which telegraph lines are exposed in the absence of precautionary measures. It appears that in the summer of 1859 a very severe storm occurred in Jersey. The land wires were struck by a flash of lightning; a portion of it rushed into the office, and destroyed the instruments, while the other portion found its vent in two places, producing small punctures in the insulated wire, and the remainder of it disappearing in the cable. The fault in the land wires were very soon found out, and still remained giving a resistance equal to 160 miles without getting better or worse. It appears that the lightning before it produced the fault in the cable must have ran along it for some sixteen miles; it then found, as Mr. Preece supposed, a weak spot, and made its way out. Mr. Preece, in reply to the interrogatories of the members of the Government committee, proceeds:—

Do you suppose that there was an eccentric part where the wire was nearer to the water than at any other place ?—Most probably, or it may be an air-hole in the gutta-percha; but it is not a serious fault in such a short circuit; that is the only instance I have experienced of a cable being seriously damaged by lightning. There is an effect in one of the specimens I have produced before the committee which I can only attribute to lightning; at one end of the wire it appears to have been a good deal blown out. Do you imagine that was produced by a thunderstorm ?—There was a thunderstorm between the break and the time it was repaired; it has such a peculiar effect that I attribute it to lightning. If lightning passed along the wire would it not escape at the part where it had the nearest access to water ?—Yes. This specimen looks like the inside of a fuse after it is discharged ?—Yes, just as if it had been fused. Do you adopt any special precautions where submarine cables approach the land ?—I have not hitherto done so, but I have ordered lightning-conductors for each shore end, and intend fixing them. (Mr. Preece then describes the apparatus he proposed to adopt being the same as that already described by Mr. Latimer Clark in his evidence.) Examination continued: You do not mind the coil being fused ?—No; we have always spare instruments, and we find more accidents and derangements arise from the use of lightning-conductors than benefit. You would only adopt lightning-conductors to submarine cables, but in those cases you would invariably use them ?—Yes. Did the lightning appear to enter at the underground wires ?—Yes. Not forming a connection with the underground wire ?—No; it appears to have entered the underground wire itself. Does the underground wire run to the office the whole distance ?—Yes; there is no wire above ground between the office and the sea. How can you account for that ?—The hill upon which the lightning seems to have struck is a granite hill; the wire goes under the road to the top, and the lightning seems to have struck the top of this hill. There is a brook running down one side of the hill, and the lightning seems to have struck somewhere near that spot; at that spot it seems to have gone into the wire; the mark of its going into the wire is at that very place; it has a certain peculiar appearance that we have often noticed in accidents to underground wires from lightning; they have a peculiar look as if they had been burst outward; in this case it seemed to take an opposite direction. Is not that the appearance it generally puts on (handing the witness a specimen of core injured by lightning) ?—Yes, it is very similar to that. This shows as if it had come out of the wire; but this, on the contrary, was like a crater, indented just in the opposite way. Did you cut the gutta-percha out where it was indented ?—Yes, we took a piece out. Did you find where it was indented that the copper was fused ?—Yes, it was burnt as if a blow-pipe flame had been acting upon it. There was also a spot at the bottom of the hill where it had evidently got out; and there is a fault existing in the cable, which I have not the slightest doubt is something similar to that. It is a fault so trivial in amount that we have paid no attention to it.

Mr. C. W. Siemens, F.R.S., in his examination, states:—

With regard to the injury occurring to these cables by lightning, it is not possible to make such arrangements on shore as to avoid the possibility of those injuries by means of lightning-conductors ?—I think there are several means by which those dangers might be avoided. The first is, to put a good lightning-discharger near the place of the landing of the cable. It is not sufficient, I consider, to place such a lightning-discharger near the station, because lightning, striking the suspended land wire, will not find sufficient discharge at the station, but will discharge in both directions, and the cable may be injuriously affected by such discharge. A very safe way of avoiding the lightning discharges upon the cable, where there are short land lines connected with them, is, in my judgment, a wire suspended in contact with the earth over the land wire in connection with the cable. Such an arrangement would be very inexpensive.

It is gratifying to find that where efficient dischargers are employed the cables have escaped danger. Mr. Buffleb, the electrician to the Levant Submarine Telegraph Company, in a communication from Chios, states that the company's cables had, for the third time, been saved from destruction owing to the employment of electric conductors. During a heavy thunderstorm which passed over the island of Metelin, eight of the poles were completely destroyed, and the electric fluid passed over the line-wire into the cable-box, where it was fortunately arrested from entering the cable by the fusion which had taken place between the upper and lower plates of the discharger.



The above illustration and the following description of the apparatus (supplied by Messrs. Siemens, Halske, & Co.) will enable our readers to understand its construction and action:—

This instrument consists of a large metallic "ground," or "earth" plate, E, so called from being brought into connection with the wires leading to the earth, and one or more smaller iron plates, L and L, called "line." plates, each line plate being connected with one of the lines entering the station and with its respective instrument. The whole of these plates are insulated from each other by the interposition of vulcanite; but the under surface of the line plates are brought into such close proximity with the upper surface of the earth plate as to leave a very small space of air between them.

The metal parts are varnished to prevent rusting. On account of the large metal surfaces standing opposite each other, and separated only by a thin space of air, small as well as heavy charges of atmospheric electricity in the line pass easily from the line plate to earth through the medium of air, which is impenetrable by the electricity used in working the line.

It sometimes happens that small particles of metal are separated from the plates by heavy discharges of atmospheric electricity, which, though they form metallic contact between line and earth in the station, do not, at least, make the discharger unfit to lead off the dangerous and destructive effects of succeeding discharges, as is the case with dischargers with points, which is very important; such particles are, however, easily removed by lifting the upper or line plate, when the surfaces can be dusted, and such particles of metal removed without disturbing the connections.

These lightning dischargers are generally made with two line plates, because, on a single wire line two line wires enter each intermediate station; but they are also made with only one line plate for end stations, or with three or more, as may be required, the earth plate being decreased or increased accordingly.

STENOGRAPHY AND TELEGRAPHY.

During the past two months a very interesting discussion has been carried on in our columns, under the heading of "Telegraphic Feats," from which good, no doubt, will arise, as it has brought the merits of different inventions into wholesome contrast. Our correspondents (generally persons in the service of telegraph companies) have evinced a very natural partiality for the system and apparatus which they each use, and, notwithstanding that great discrepancy is manifest in the statements as to the rates of transmission per minute or hour, attributed to the several instruments employed, they all agree that, in this respect, much depends upon the capacity of the clerk or clerks at the sending and receiving stations. The dispatch and accuracy with which long and important speeches of members of parliament and other notabilities, are forwarded to the press, is truly marvellous. The addresses of Messrs. Bright and Scholefield, delivered before their constituents in the Town-hall, Birmingham, on the 26th January, consisting of about 12,000 words, were transmitted to the London papers in five hours, and when in type occupied six columns of the Times; the Queen's Speech on the occasion of the opening of Parliament (containing 900 words) was transmitted from London to Liverpool, on the 4th February last, in nine minutes; yet some of our correspondents think this "poor speed." The means by which these extraordinary results are attained, might be greatly simplified and expedited by the employment of stenographers as telegraphists. An important consideration in the present day is how to transact the greatest amount of business in the shortest possible space of time, and, in cases like those to which we have alluded, every hour saved is of the utmost consequence.

At present it is customary for reporters to transcribe their verbatim short-hand notes into long-hand, before placing copy in the hands of the telegraph clerks, a process which occupies, perhaps, one-half the time intervening between the delivery of a speech, and its transmission to any remote locality. Now, were telegraph clerks acquainted with the principles of stenography, they would be (if otherwise well-educated) capable of sending reports from short-hand notes, and thereby effect an immense saving of time and labour; one transcription, and that at the receiving station, for the printer, proving all that is needful. It seldom happens that more than five or six wires are used on these occasions, and it would be well for the managers of large telegraph establishments to consider whether it would not be profitable to keep a staff of qualified clerks for this description of business. Another, and to all intents a more efficient plan to facilitate the speedy reporting of political and after-dinner harangues, would be for our companies to supply them to the daily papers at their own cost, *à la Reuter.* They could then, by offering adequate remuneration, secure the services of clerks qualified to perform the duties of reporters and transmitters. To illustrate our proposition, we will suppose that a public demonstration is about to take place at Southampton. The telegraph company whose lines extend to that district will instruct, say, six reporting clerks to attend. After the proceedings commence, each one, in order previously arranged, could leave the meeting half-hourly with his notes, proceed to the instrument-room, transmit the same, and return to relieve a compeer at the meeting. They would thus be able to forward their report direct to its destination by the wire, save the delay and cost of transcription, and avoid any confusion or hesitation in deciphering bad manuscript. These suggestions, which we shall enlarge upon at some future time, could be adopted where the Morse and bell instruments are used, by those who employ Hughes' printing machine, and with great effect by the Bonelli Company, in which latter case writing, after the short-hand notes, could be dispensed with entirely. The now general system of realising any given plan by a division of labour, has begotten methods of action which, in particular cases, frustrate the end in view. Six clerks, possessing the qualifications we have enumerated, could report and transmit a speech, by this plan, quicker and cheaper than twelve persons proceeding in the present routine manner. These recommendations are inapplicable to the ordinary commercial business of the telegraph, where it is necessary to have every despatch written in full by the person for whom it is sent, but for newspaper work the employment of stenographers by telegraph companies, certainly appears to possess many and decided advantages. They need not be kept exclusively for reporting, but if a limited number were placed on the staff, they could, whenever required, betake themselves to any district, transact their special business, and return to their ordinary avocations.

THE INTERNATIONAL EXHIBITION, 1862.

(Continued from page 164.)

The Universal Private Telegraph Company [Professor Wheatstone, Juror] (United Kingdom, 2,978) exhibit a magneto-electric dial instrument, invented by Professor Wheatstone. In the transmitting instrument the armature of a permanent magnet is kept in continuous motion by the hand of the operator, or by any other moving power; and finger-stops corresponding with the letters on the dial of the telegraph, on being respectively pressed down, determine the passage of the currents in the proper number and order to produce the required motion of the index at the receiving end. By this means the operator can act on the finger keys with perfect facility, however large the magnets and armatures may be, which is not the case when the armature itself is required to be stopped. The continuous motion of the armature has another great advantage over the old starting and stopping system; it avoids the risk already alluded to, that both on stopping and starting the operator will move his handle too slowly, and that he will move it at a different

speed, when few or many letters have to be passed. Every alteration of speed is, of course, accompanied by an alteration of the strength of the current sent, whereas in Professor Wheatstone's instrument the motion of the armature is perfectly regular, and consequently equal currents are sent at all times.

The arrangement of the induction coils and armature is peculiar. Four soft-iron cylindrical cores with their coils are fixed to each pole of a permanent magnet, so that their centres are equidistant from each other in the circumference of a circle. An axis passing through the centre of this circle carries a soft-iron armature, the breadth of which is a little greater than the distance between two adjacent cores. Thus, when the armature revolves it approaches one pole as it recedes from that diagonally opposite. The currents induced simultaneously in the two corresponding coils concur to produce a current in one direction through the line wire. During each revolution of the armature four currents are induced, all equal, each resulting from two coils.

The arbor, which is geared with the axis of the armature, carries a brass wheel, on the periphery of which are fifteen little teeth spaced equally, but at some distance apart; this wheel continually revolves. An armature with an index attached is centred on this arbor, and can move freely round it, but so long as a spring catch on its end is in contact with one of the teeth of the above-named wheel the arm revolves along with the wheel. The arm and wheel form part of the telegraphic circuit, which is complete so long as they revolve together, but is interrupted whenever the catch is not in contact with any tooth of the wheel. Thirty finger-stops are so placed that the depression of any one of them shortly afterwards stops the index arm, the spring catch allows the wheel to pass, and the circuit is broken, except for the very short moments when a tooth touches the spring catch in passing. These moments correspond to a position of the armature when no current is induced, and the contacts might be allowed to take place without detriment. The circuit in the instrument exhibited is, however, broken in a second place by a little spring and lever, the latter of which is thrown back by coming in contact with the finger-stop.

The transmission of currents into the line is, therefore, entirely interrupted so long as the motion of the index arm is arrested. When the stop rises the little lever returns to its contact at once, but the circuit is only complete when contact is made between the sending arm and one of the little catches on the periphery of the revolving brass wheel at a moment corresponding to that of the inversion of the current; thus, imperfect currents are prevented from entering the circuit, and the opposite current to that last sent before the arm was stopped is first sent when it starts again. So long as no key is down currents continue to pass into the circuit; but to avoid useless currents, adding unnecessarily to the chances of failure, a contrivance is adopted by which any one of the finger-stops which may have been depressed remains so, even when the finger is removed, until another stop is put down, when the former is restored to its normal position. This is effected by an endless chain passing round a series of friction rollers so placed as to form a circle concentric with the circle in which the finger-stops are arranged, and having just "slack" enough to allow of the depression of one stop only. The finger-stops are so constructed, that when any one of them is depressed, it presses against the endless chain and tightens it, and when another stop is subsequently depressed it bears in like manner against the chain, so that the flexure made by the former stop is obliterated, and that stop lifted to its normal position.

In the receiving instrument both the propelment and the electro-magnetic arrangements are novel and ingenious. To form the latter, two magnetic needles or bars, with their poles in opposite directions, are placed near each other on opposite sides of, and parallel to, the axis on which they rock; two straight electro-magnets are placed one on each side of the axis of motion of the needles, and parallel to it. When a current arrives through the coils of these electro-magnets the dissimilar poles of the two needles are simultaneously acted on, so that each of their poles is attracted by one pole of one electro-magnet, and repelled by one pole of the other electro-magnet: the attracting and repelling motions all concur in rocking the pair of magnets on the axis in the same direction. The magnets are curved in towards each other towards the middle of their length, so as to throw their weight nearer the axis of motion. The attraction from the residual magnetism remaining in the electro-magnets after the current has ceased, is sufficient to hold the magnets firmly on one side.

A very similar arrangement with several magnets, and coils round the prolongation of one axis is used for Professor Wheatstone's Steinheil receiving instrument employed with the automatic sender.

In the propelment the axis of the propelling wheel, instead of being fixed, is attached to a short rocking lever, moved backwards and forwards by a pin connected with the magnetic armature. Two fixed pallets act on teeth at opposite points of the circumference of the wheel, to which a rotatory motion is given by its being moved to and fro between the two pallets by the rocking lever. The motion is limited by two fixed pins, against which the propelling wheel impinges at the opposite limits of its oscillation. Each pallet consists of a very light spring placed tangentially to the circumference of the wheel; it yields readily to the tooth passing beneath when the opposite tooth is propelled by the other pallet, and then falls into its place ready to propel the tooth which has passed beneath it. To prevent the oscillatory motion of the wheels from being communicated to the index, the axis of the latter is detached from that of the former, and is driven by a pin. This propelment moves the index with great regularity; no tooth can slip, and a very weak current is sufficient to work the index. All the parts are constructed with extraordinary delicacy and lightness: indeed, the workmanship of this receiving instrument is unrivalled among the telegraphic apparatus. Two of these little instruments worked perfectly through a circuit of resistance equal to that of about 375 miles of No. 8 iron wire. One of the instruments worked perfectly through 450 miles. They have been practically used on circuits of more than 100 miles. This apparatus has great advantages over even good instruments of the old class, in which the coils or the armatures are alternately stopped and started. These instruments are now extensively adopted in this country, especially for private communication between docks, warehouses, shops, offices, &c.

H. Wilde, Manchester (United Kingdom, 2,992), exhibits magneto-electric dial instruments with two forms of transmitter. In one he has adopted the arrangement of coils and armature invented by Professor Wheatstone, and shown in the instrument exhibited by the Universal Private Telegraph Company. Mr. Wilde, moreover, provides for the rapid and equal motion of his armature by using the continuous driving motion of a strap worked by a treadle, but instead of simply breaking the connection between the line and the coils during any pause at a letter or between words, Mr. Wilde arrests his armature by the depression of finger-stops. When the armature is so arrested the driving-band simply slips on its pulley; so soon as the finger is removed from the stop it rises, and the armature is allowed to start at full speed, being driven by the band. Mr. Wilde, to allow of the sudden start and stoppage of his armature, has been forced to make it extremely light, and by so doing has very much weakened the induced currents.*

The other form of transmitter is worked with a reciprocating motion by hand, and is certainly superior to Mr. Wilde's circular form. In it a reciprocating rectilinear motion is substituted for the usual circular motion of the axial arm. This rectilinear motion is converted into a circular motion by a nut on a double or triple threaded screw; this screw carries two armatures round in front of two pair of coils on two compound horseshoe magnets; the one armature approaches the centre of its coils, while the other recedes. The coils are connected in series, so that the currents induced by both armatures agree; and this arrangement produces a succession of equal and opposite currents. The nut which drives the screw is driven backwards and forwards from one position to another by one hand, and is abruptly stopped in each fresh position by being brought sharply against a pin previously placed with the other hand in a hole opposite the corresponding letter. Thirty letters or symbols are marked down one side of the slot in which the nut moves, and thirty similar letters or symbols up the other side; the nut must always be moved down to the letters on one side, and up to the letters on the other, passing to the extreme end in each case before changing the direction of the motion; in fact, the nut must work round and round the alphabets. Mr. Wilde considers this plan cheaper than the usual circular arrangement.

The receiving instrument has considerable merit; the propelment is well devised, and the workmanship of the instrument is good. It contains an alarum which is started by the step-by-step propelment without any separate electro-magnet. It is driven by a barrel-

* The above is the opinion of the writer and of several of the other jurors. Mr. Wilde dissents from this opinion, and quotes Barlow, Kater, and other authorities, to show that a light armature may be as good as a heavy one; the writer is, however, of opinion that, although a light armature of good form may be better than a heavy armature of bad form, nevertheless, when the material is in each case disposed in the most effective manner, the heavy armature will always be much superior to the light armature.

spring and clockwork, and continues ringing until stopped by hand. The propelment used may be described as follows:—

Two ratchet or star wheels, each with fifteen pointed teeth, are geared together by two ordinary spur-wheels of equal diameter, one on the axis of each star-wheel. The two faces of each tooth of the star-wheels form two sides of an equilateral triangle, and the diameter of the wheels is such that the teeth just clear one another. The dial-index or pointer is on the axis of one of the wheels; a little pin moved by the armature of an electro-magnet oscillates between the two star-wheels, and causes their revolution; when moving to the right it bears against, say, the under inclined surface of a tooth of the right-hand wheel, and by so doing turns that wheel from left to right one-thirtieth of a revolution; the other star-wheel, of course, moves an equal distance from right to left; when the pin comes back towards the left it leaves the right-hand star-wheel, and presses against the under inclined surface of a tooth on the left-hand wheel, turning it one-thirtieth of a revolution from right to left, while, owing to the gearing, the right-hand wheel moves on an equal distance in the same direction as before, and the under surface of a fresh tooth on this wheel is now in a position to be acted on; thus, the slight to-and-fro motion of the pin is converted into a step-by-step rotation of the index on the right-hand wheel. In this arrangement there are no adjustments, spring-stops, or pallets; it is impossible for the index to fly round so as to slip a tooth, for the little pin is always in the way of either one or other star. The friction caused by the gearing, and by the indirect action of the pin on the star-wheels, is probably greater than that of Wheatstone's or Siemens' propelments. Mr. Wilde's propelment works well, however, even at very high speeds.

With the reciprocating transmitter, Mr. Wilde's dial instrument worked correctly with a resistance of about 140 statute miles of No. 8 iron wire in circuit. It was admitted that the circular transmitter would not have worked through nearly so large a resistance, but Mr. Wilde considered this due to no defect of design, but to the fact that the instrument exhibited was the first instrument of the kind made.

(b.) *Step-by-step Letter-showing Instrument worked by Voltaic Induction Currents.*—A dial instrument of this kind is shown by T. Allan, M. (United Kingdom, 2,850).

The transmitter has four electro-magnetic primary and secondary induction coils on four straight soft-iron cores, so placed as to form the sides of a square; the four coils are so connected as to act like one. The instrument has a dial with stops corresponding to the letters of the alphabet; a train of clockwork drives an arm on the axis of this dial, and a notched wheel, by which the current in the primary coil is reversed twenty-six times during each revolution of the axial arm. When a stop is depressed the arm is arrested by it, and stops the clockwork and reversing wheel. They start again when the stop is released, and continue to send reversals through the primary coil, until the arm is arrested by the depression of another stop. The secondary coil sends a number of signals along the line corresponding to the number of reversals in the primary coil, and so works the step-by-step receiving instrument. The closed rectangle of soft-iron, although it exhibits no external sign of polarity, is said to be far preferable to a straight or horseshoe core for the induction coils. In corroboration of this opinion experiments made by the exhibitor were quoted, from which it appeared that when the four coils were arranged in a straight line the receiving instrument could only be worked with about one-half of the resistance in circuit, which might be introduced when they were arranged in a continuous square, and that the presence of even a piece of cardboard at one corner interrupting the continuity reduced the resistance through which signals were received by one-third. A simple induction coil made on this plan is also exhibited by Mr. Allan.

The index of the receiving instrument is worked by a very simple propelment. The armature of the receiving electro-magnet moves a little toothed wheel to and fro between fixed stops so placed that they each turn the wheel one twenty-sixth of a revolution; the index is on one end of the axis of this little toothed wheel, and the axis is made of such length that the slight play required to allow the to-and-fro motion of the wheel is quite insensible at the index end. The writer considers that it is just possible for the index to slip past the stops when currents cease to be received. The receiving instrument is otherwise very similar to that exhibited in 1851, and could, of course, be worked by magneto-electric or simple battery currents.

(c.) *Step-by-step Letter-showing Instruments worked by Voltaic Currents.*—The Universal Private Telegraph Company [Professor Wheatstone, Juror] (United Kingdom, 2,978) exhibit a simple and excellent transmitter, by which alternately inverted currents are sent. The letter circle or wheel is composed of a number of flexible spokes or radii corresponding to the different letters or signs, and proceeding from a common central axis, which also carries a spur-wheel. A finger-pin is fixed on the end of each spoke. When any letter is to be sent the corresponding finger-pin is pressed down, deflecting the spoke, and the axis is then turned round by the finger until a prolongation of the finger-pin comes in contact with a fixed stop, when the required number of contacts will have been sent, and the spoke may be allowed to rise. The required succession of contacts is made in a very simple manner by a second axis making half a revolution for each letter, and turned by a pinion driven from the spur-wheel on the main axis.

This transmitter is equally well adapted for working a step-by-step instrument with volta-induction currents. The battery current passes through a short circuit at the moment of inversion, so as to avoid the spark, which would otherwise occur when the circuit is broken.

E. Tyer (United Kingdom, 2,977) exhibits a step-by-step dial instrument worked with voltaic currents. His sending instrument is arranged to send reverse currents, as in the latest French instruments of this kind. He uses rubbing contacts made by a spring from a radial arm, instead of the dead pressure contacts used in France. He drives his radial arm by clockwork, and stops it by keys opposite the required letter, instead of turning it by hand. The finger-keys are compactly arranged in parallel rows, an arrangement which seems preferable to the circular one.

The propelment of his receiving dial consists of two light ratchet-wheels on the axis of the index, with their teeth on the face of the wheels, instead of on the periphery. These teeth face one another, and the inclined surfaces of the teeth, which are nearly opposite one another, both converge, so that a little pin, worked to and fro between the wheels by the armature, moves the axis round step by step, first pressing on the inclined surface of one tooth of one wheel, and next on the corresponding surface of a tooth in the other wheel; the points of the teeth of one wheel are opposite the centres of the inclined surfaces of the teeth of the other wheel. This propelment seems good, but the arrangement of the receiving electro-magnet and armature used with it is not satisfactory, and a trial of the instrument gave indifferent results. Mr. Tyer observed, however, that this was the first instrument of the class made by him, and intended rather as a model than for actual work. He is of opinion that he could construct instruments on this plan equal to any others.

Digney Brothers & Co., Paris, M. (France, 1,414), exhibit a step-by-step dial instrument worked by voltaic currents. Their transmitting apparatus is very similar to that shown by M. Bréguet, Paris, M. (France, 1,413), and long used in France. A radial sending arm moves a disc round, in the lower surface of which a serpentine groove is cut; a lever rocking on a vertical axis is worked by a projection fitting into this groove. M. Bréguet, who works with single currents and interruptions, has only one of these rocking levers; Messrs. Digney, who work with reverse currents, require two. The index of the receiving dial is in both instruments driven by clockwork, of which the electric current works the escapement, used instead of the propelment of the English magneto-electric instruments.

The motion of the pallet in each case is in the plane containing the axis of the escapement, instead of being in a plane perpendicular to it, as in the usual propelments and in clock escapements. Messrs. Digney use a little forked pallet in their escapement; when one of the forks moves so far on one side as to let a tooth slip, the other is in the right position to catch the next tooth, which it lets pass in its turn on coming back to the first position. M. Bréguet, instead of a forked pallet, uses a plain pallet between two ratchet-wheels, catching first one and then the other, and letting their axis make one twenty-sixth of a revolution each time.

M. Bréguet has an ingenious mode of sending the index back to the zero or cross by one touch of a button. He uses the common electro-magnet with an adjustable antagonistic spring.

Messrs. Digney use Siemens' polarized electro-magnet, which allows them to dispense in a great measure with any adjustment during use. Messrs. Digney's instrument was worked freely by three Daniell's cells, with 200 kilometres of iron wire 4 millimetres diameter in circuit.*

* This is equal to about 150 miles of No. 8 iron wire.

Neither of these instruments could be worked at the speed of the English magneto-electric instruments. In that of M. Bréguet, one contact too many is sometimes made by the rocking lever if the handle be stopped too suddenly; this lever ends in a spring, and works through a considerable space (nearly ¼ inch). It is consequently in a state of violent vibration, and, if worked too fast, springs back from the last contact, giving an interruption and a consequent extra current. Both M. Bréguet's and MM. Digney's look complicated beside the magneto-electric instruments, but their price is considerably less. Messrs. Digney's receiver and transmitter are supplied complete for £10.

(To be continued.)

THE DOT AND LINE ALPHABET.

The following humourous and entertaining communication was addressed to the *Atlantic Monthly*, by the Rev. Edward E. Hale, on the variety of purposes to which the dot and line alphabet might be employed. We understand that communications were carried on with ease and accuracy, between the vessels engaged in laying the Persian Gulf cable, by the exhibition of light, at intervals corresponding with the dot and line alphabet; a momentary appearance of the light indicating a *dot*, and one of a short duration a *line* or *dash*:—

Please to understand, then, ignorant reader, that this curious alphabet reduces all the complex machinery of Cadmus, and the rest of the writing-masters, to characters as simple as can be made by a dot, a space, and a line, variously combined. Thus, the marks - — designate the letter A. The marks — - - - designate the letter B. All the other letters are designated in as simple a manner. Now I am stripping myself of one of the private comforts of my life, (but what will one not do for mankind?) when I explain that this simple alphabet need not be confined to electrical signals. *Long* and *short* make it all,—and wherever long and short can be combined, be it in marks, sounds, sneezes, fainting-fits, canes, or children, ideas can be conveyed by this arrangement of the long and short together. Only last night, I was talking scandal with Mrs. Wilberforce, at a summer party at the Hammersmiths. To my amazement, my wife, who scarcely can play "The Fisher's Hornpipe," interrupted us by asking Mrs. Wilberforce if she could give her the idea of an air in "The Butcher of Turin." Mrs. Wilberforce had never heard that opera, indeed, had never heard of it. My angel-wife was surprised, stood thrumming at the piano, wondered she could not catch this very odd bit of discordant accord at all, but checked herself in her effort, as soon as I observed that her long notes and short notes, in their tum-tee-tee, tee-tee, tee-tum-tum, meant "He's her brother." The conversation, on her part, turned from "The Butcher of Turin," and I had just time, on the hint thus given me by Mrs. I., to pass a grateful eulogium on the distinguished statesman whom Mrs. Wilberforce, with all a sister's care, had rocked in his baby-cradle, whom, but for my wife's long and short notes, I should have clumsily abused among the other statesmen of the day.

You will see in an instant, reader, that it is not the business simply of "operators" in telegraphic dens to know this Morse alphabet, but your business, and that of every man and woman. If our school-committees understood the times, it would be taught, even before phonography, or physiology, at school. I believe both these sciences now precede the old English alphabet.

As I write these words, the bell of the South Congregational strikes dong, dong, dong,—dong, dong, dong,—dong, dong, dong. Nobody has unlocked the church-door. The old tin sign, "In case of fire, the key will be found at the opposite house," has long since been taken down, and made into the nose of a waterpot. Yet there is no Goody Two-Shoes locked in. No! But, thanks to Dr. Channing's Fire Alarm, the bell is informing the South End that there is a fire in District dong, dong, dong,—that is to say District No. 3. Before I have explained to you so far, the "Eagle" engine, with a good deal of noise, has passed the house on its way to that fated district. An immense improvement this on the old system, when the engines radiated from their houses in every possible direction, and the fire was extinguished by the few machines whose lines of quest happened to cross each other at the particular place where a child had been building cob-houses out of lucifer-matches in a paper warehouse. Yes, it is a very great improvement. All those persons, like you and me, who have no property in district dong-dong-dong, can now sit at home at ease, and little need we think upon the mud above the knees of those who have property in that district, and are running to look after it. But for them the improvement only brings misery. You arrive wet, hot or cold, or both, at the large District No. 3, to find that the lucifer-matches were half-a-mile from your store, and that your own private watchman, even, had not been waked by the working of the distant engines. Wet property-holder, as you walk home, consider this. When you are next in the Common Council, vote an appropriation for applying Morse's alphabet of long and short to the bells. Then they can be made to sound intelligibly. Daung ding ding, ding, ding daung, daung daung daung, and so on, will tell you, as you wake in the night, that it is Mr. B.'s store which is on fire, and not yours, or that it is yours, and not his. This is not only a convenience to you and a relief to your wife and family, who will thus be spared your excursions to unavailable and unsatisfactory fires, and your somewhat irritated return, but it will be a great relief to the Fire Department. How placid the operations of a fire where none attend except on business. The various engines arrive, but no throng of distant citizens, men and boys, fearful of the destruction of their all. They have all roused on their pillows to learn that it is No. 530, Pearl-street, which is in flames. All but the owner of No. 530, Pearl-street, have dropped back to sleep. He alone has rapidly repaired to the scene. That is he who stands in the uncrowded street with the chief engineer, on the deck of No. 18, as she plays away. His property destroyed, the engines retire; he mentions the amount of his insurance to those persons who represent the daily press, they all retire to their homes; and the whole is finished as simply, almost, as was his private entry in his day-book the afternoon before. This is what might be, if the magnetic alarm only struck *long* and *short*, and we had all learned Morse's alphabet. Indeed there is nothing the bells could not tell; if you would only give them time enough. We have only one chime for musical purposes, in the town. But, without attempting tunes, only give the bells the Morse alphabet, and every bell in Boston might chant, in monotone, the words of "Hail Columbia!" at length, every fourth of July. Indeed, if Mr. Barnard should report any day that a discouraged prentice-boy had left town for his country home, all the bells could instantly be set to work to speak articulately, in language regarding which the dullest imagination need not be at loss,

"Turn again, Higginbottom,
Lord Mayor of Boston!"

I have suggested the propriety of introducing this alphabet into the primary schools. I need not say I have taught it to my own children, and I have been gratified to see how rapidly it made head against the more complex alphabet in the grammar schools. Of course it does. An alphabet of two characters, matched against one of twenty-six, or of forty odd, as the very odd one of the phonotypists employs! On the Franklin medal-day I went to the Johnson School examination. One of the committee asked a nice girl, what was the capital of Brazil. The child looked tired and pale, and, for an instant, hesitated. But, before she had time to commit herself, all answering was rendered impossible by an awful turn of whooping-cough which one of my own sons was seized with, who had gone to the examination with me. Hawm, hem hem; hem hem hem; hem, hem; hawm, hem hem; hem hem hem; hem hem,—barked the poor child, who was at the opposite extreme of the school-room. The spectators and the committee looked to see him fall dead with a broken blood-vessel. I confess that I felt no alarm, after I observed that some of his gasps were long, and some very *staccato*; nor did pretty little Mabel Warren. She recovered her colour, and, as soon as silence was in the least restored, answered, "*Rio* is the capital of Brazil," as modestly and properly as if she had been taught it in her cradle. They are nothing but children any of them; but that afternoon, after they had done all the singing the city needed for its annual entertainment of the singers, I saw Bob and Mabel start for a long expedition into West Roxbury, and, when he came back, I know it was a long featherfew, from her prize school-bouquet, that he pressed in his Greene's "Analysis," with a short frond of maiden's hair.

I hope nobody will write a letter to *The Atlantic*, to say that these are very trifling uses. The communication of useful information is never trifling. It is as important to save a nice child from mortification on examination-day, as it is to tell Mr. Fremont that he is not elected President. If, however, the reader is

distressed because these illustrations do not seem, to his more benighted observation, to belong to the big bow-wow strain of human life, let him consider the arrangement which ought to have been made years since, for lee shores, railroad collisions, and that curious class of maritime accidents where one steamer runs into another under the impression that she is a lighthouse. Imagine the Morse alphabet applied to a steam-whistle, which is often heard five miles. It needs only *long* and *short* again. "*Stop Comet*," for instance, when you send it down the railroad line, by the wire, is expressed thus:—

. . . — . . . .

. . . . . — — . —

Very good message, if Comet happens to be at the telegraph station when it comes! But what if Comet has gone by? Much good will your trumpery message do then! If, however, you have the wit to sound your long and short on an engine whistle, thus:—Scre scre, scre; screeeee; scre scre; scre scre scre scre; scre scre—scre, scre, scre, screeeee screeeee; scre; screeeed,—why, then the whole neighbourhood, for five miles round, will know that Comet must stop, if only they understand spoken language; and, among others, the engineman of Comet will understand it; and Comet will not run into that wreck of worlds which gives the order,—with his nucleus of hot iron and his tail of five hundred tons of coal. So, of the signals which fog-bells can give, attached to lighthouses. How excellent to have them proclaim through the darkness, "I am Wall!" Or of signals for steam-ship engineers. When our friends were on board the "Arabia" the other day, and she and the "Europa" pitched into each other,—as if, on that happy week, all the continents were to kiss and join hands all round—how great the relief to the passengers on each, if, through every night of their passage, collision had been prevented by this simple expedient! One boat would have screamed, "Europa, Europa, Europa, Europa," from night to morning, and the other, "Arabia, Arabia, Arabia," and neither would have been mistaken, as one unfortunately was, for a lighthouse. Any passenger who has ever had a state-room next the whistle will testify to the sense of secure comfort this nightly chorus would give him.

The long and short of it is, that whoever can mark distinctions of time can use this alphabet of long-and-short, however he may mark them. It is, therefore, within the compass of all intelligent beings, except those who are no longer conscious of the passage of time, having exchanged its limitations for the wider sweep of eternity. The illimitable range of this alphabet, however, is not half disclosed when this has been said. Most articulate language addresses itself to one sense, or at most to two, sight and sound. I see, as I write, that the particular illustrations I have given are all of them confined to signals seen or signals heard. But the dot-and-line alphabet, in the few years of its history, has already shown that it is not restricted to these two senses, but makes itself intelligible to all. Its message, of course, is heard as well as read. Any good operator understands the sounds of its ticks upon the flowing strip of paper, as well as when he sees it. As he lies in his cot at midnight, he will expound the passing message without striking a light to see it. But this is only what may be said of any written language. You can read this article to your wife, or she can read it, as she prefers; that is, she chooses whether it shall address her eye or her ear. But the long-and-short alphabet of Morse despises such narrow range. It addresses whichever of the five senses the listener chooses.

This fact is illustrated by a curious set of anecdotes—never yet put in print, I think—of that critical despatch which in one night announced General Taylor's death to this whole land. Most of the readers of these lines probably read that despatch in the morning's paper. The compositors and others had read it. To all of them it was a despatch to the eye. But half the operators at the station *heard* it ticked out, by the register stroke, and knew it before they wrote it down for the press. To them it was a despatch to the ear. My good friend Langenzunge had not that resource. He had just been promised, by the General himself (under whom he served at Palo Alto), the office of Superintendent of the Rocky-Mountain lines. He was returning from Washington, over the Baltimore and Ohio railroad, on a freight-train, when he heard of the President's danger. Langenzunge loved Old Rough and Ready, and he felt badly about his own office, too. But his extempore train chose to stop at a forsaken shanty village on the Potomac, for four mortal hours, at midnight. What does he do but walk down the line into the darkness, climb a telegraph-post, cut a wire, and apply the two ends to his tongue, to *taste*, at the fatal moment, the words, "Died at half-past ten." Poor Langenzunge! he hardly had nerve to solder the wire again. Cogs told me that they had just fitted up the Naguadavick stations with Bain's chemical revolving disc. This disc is charged with a salt of potash, which, when the electric spark passes through it, is changed to Prussian blue. Your despatch is noiselessly written in dark-blue dots and lines. Just as the disc started on that fatal despatch, and Cogs bent over it to read, his spirit-lamp blew up, as the dear things will. They were beside themselves in the lonely, dark office; but, while the men were fumbling for matches, which would not go, Cog's sister, Nydia, a sweet blind girl, who had learned Bain's alphabet from Dr. Howe at South Boston, bent over the chemical paper, and *smelt* out the prussiate of potash, as it formed itself in lines and dots to tell the sad story. Almost anybody used to reading the blind books can read the embossed Morse messages with the finger; and so this message was read at all the midnight way-stations where no night-work is expected, and where the companies do not supply fluid or oil. Within my narrow circle of acquaintance, therefore, there were these simultaneous instances where the same message was seen, heard, smelled, tasted, and felt. So universal is the dot and line alphabet; for Bain's is on the same principle as Morse's.

The reader sees, therefore, first, that the dot and line alphabet can be employed by any being who has command of any long and short symbols; be they long and short notches, such as Robinson Crusoe kept his accounts with, or long and short waves of electricity, such as those which Valentia will send across to the Newfoundland Bay, so prophetically and appropriately named "The Bay of Bulls." Also, I hope the reader sees that the alphabet can be understood by any intelligent being who has any one of the five senses left him; by all rational men, that is, excepting the few eyeless deaf persons who have lost both taste and smell in some complete paralysis. The use of Morse's telegraph is by no means confined to the small clique who possess or who understand electrical batteries. It is not only the torpedo or the *Gymnotus electricus* that can send us messages from the ocean. Whales in the sea can telegraph as well as senators on land, if they will only note the difference between long spoutings and short ones. And they can listen, too. If they will only note the difference between long and short, the eel of ocean's bottom may feel on his slippery skin the smooth messages of our presidents, and the cat-fish, in his darkness, look fearless on the secrets of a queen. Any beast, bird, fish, or insect, which can discriminate between long and short, may use the telegraphic alphabet, if he have sense enough. Any creature, which can hear, smell, taste, feel, or see, may take note of his signals, if he can understand them. A tired listener at church, by properly varying his long yawns and his short ones, may express his opinion of the sermon to the opposite gallery before the sermon is done. A dumb tobacconist may trade with his customers in an alphabet of short-sixes and long-nines. A beleaguered Sebastopol may explain its wants to the relieving army beyond the line of the Chernaya, by the lispings of its short Paixhans and its long twenty-fours.

THERMO-ELECTRIC CURRENTS IN CIRCUITS OF ONE METAL.

READ BEFORE THE BRITISH ASSOCIATION,

By Fleeming Jenkin, Esq.

The investigations of the author of the following paper into the phenomena which characterise the development of thermo-electric currents in a circuit of one metal by the application of heat, are exceedingly interesting and instructive, and we think the reproduction of the Paper in our columns will be acceptable to those of our readers who have not the opportunity of perusing the expensive transactions of the British Association, before which it was read.

Last year I had the honour of directing the attention of the Association to the fact, that an electric current of considerable intensity may be obtained in a circuit of one metal by the application of heat to one or the other side of an interruption in the wire composing the circuit. The experiment is most simply performed by looping together the two ends of two perfectly similar wires connected to the terminals of a galvanometer, and heating one of

the loops to a white or red heat in a spirit-lamp, or Bunsen's burner. If the one loop rests very lightly on the other a current will be obtained, which in the copper wires will flow from the hot to the cold loop across the joint with sufficient intensity to deflect a moderately sensitive galvanometer, even with a resistance in circuit equal to 1000 miles of No. 16 copper wire.

The electromotive force of the combination is about one-tenth that of a Daniell's cell. With two iron loops a permanent current in the opposite direction is obtained, flowing from cold to hot across the joint, but the electromotive force in this case is very much smaller.

When the loops are drawn tightly together the current ceases, but reappears as soon as the strain is slackened.

I was at the time unable to show the connection between these singular currents and other electrical phenomena, but I am now, in consequence of further experiments undertaken for the Association, able to point out that connection.

The currents were clearly not due to chemical action on the wires; for, in the first place, currents of considerable strength were obtained from two perfectly homogeneous platinum wires, flowing from hot to cold across the loose contact; and in the second place, the direction of the current was different in copper and iron, whereas the chemical action undergone by the wire was alike in the two cases.

The researches of Becquerel, Pouillet, Bluff, Hankel, and Grove were examined, to see whether the electricity produced during combustion, or the properties of flame, would account for the currents, but it was found that all the electrical effects produced by flame could be divided into two classes: first, phenomena depending on the relative position of the two wires in the flame; and secondly, phenomena depending on the voltaic couple formed by the metals used, and the hot vapour acting as an electrolyte between them. My results were independent of the position of the wires in the flame, and could not be accounted for by supposing these wires to form a voltaic couple, inasmuch as though in some cases, where wires of two metals were looped together as described, the current flowed from the metal most attacked across the imaginary electrolyte to the other wire, in other cases it flowed in the opposite direction.

It remained to be seen whether the currents might not have a thermo-electric origin. Last year I imagined that the effect observed might be directly due to discontinuity, but that idea was dispelled by some experiments with loose contacts between wires of different metals, which have thrown great light on the question.

Loops of iron, silver, platinum, gold, and copper wires were combined two by two in all the possible arrangements, and the currents measured which were obtained when one or the other or both loops were heated with loose and tight contacts between them.

A Table was thus formed, which is appended to the present paper.

The resistance of the circuit was so large (2050×10^6, Weber's absolute $\frac{\text{foot}}{\text{seconds}}$) that the inherent resistance of the joint and of the different short wires used in each experiment could be neglected, and the deflections obtained on a reflecting galvanometer could be taken as approximatively proportional to the electromotive force of each combination. The common thermo-electric currents produced by the metallic contact between dissimilar wires almost vanish in comparison with those produced by the loose contacts.

I need not present a complete analysis of the Table, but will speak only of the combination of iron and copper with which the most remarkable results were obtained. When the usual tight metallic contact was made between these two wires and the two loops equally heated, the current first flowed from copper to iron across the joint, and then as the temperature rose ceased altogether, and finally, at a red or white heat, flowed from iron to copper. The maximum deflection obtained in either direction was three divisions. These deflections showed the celebrated inversion discovered by Cumming.

If the pressure between the loops was relaxed, the current ceased altogether; but when the loops were moved, so that the copper became red-hot while the iron was cool, a current flowed from the copper to the iron, or from hot to cold across the joint, giving a deflection of 100 divisions; whereas if the iron was heated red-hot and the copper cooled, a current giving 90 divisions flowed in the opposite direction, or from iron to copper, but from hot to cold as before. Thus in these two cases the loose-contact currents given when one or the other loop was heated, flowed in the opposite direction between the metals, but in both cases from hot to cold across the joint, and were in each case about thirty times as great as the currents given by the thermo-electric difference between the metals.

It was found, on examining the Table, that wherever copper appeared in conjunction with any other of the metals named, the direction of the loose-contact current could invariably be determined by the following rule:—When the copper was the hot wire, the current flowed from the copper to the other metal across the joint; but when copper was the cold metal, the current flowed from the other metal to the copper, or in both cases from hot to cold.

Exactly the contrary was found wherever iron appeared in conjunction with any of the five metals but copper; the current then always flowed from cold to hot. Two copper wires alone gave the largest deflection, of about 220 divisions; and two iron wires alone gave the next largest of those obtained where single metals only were used, but of course in the opposite direction to the deflection from copper.

It was then perceived that all these results would be explained if the thin coating of oxide on the copper wire might be regarded as a conductor with a hot and cold junction, and endowed with thermo-electric properties far more positive than the iron, while at the same time the coating of oxide on the iron wire would have to be regarded as far more negative than the copper. It was, however, difficult to suppose that two bodies so similar in some respects as the oxides of copper and iron should be at opposite extremities of the thermo-electric scale, but the following direct experiment left no doubt on my mind.

A little spiral was made of platinum wire, and a small quantity of oxide of copper laid upon it, and held in a flame till white-hot; another platinum wire was then dipped in the melted mass, when a strong current was at once observed from the hot to the cold wire, as if a loose contact had been made between two copper wires. When either of the oxides of iron was tested in a similar manner, a strong current was obtained from the cold to the hot platinum wire, as if a loose contact had been made between two iron wires.

I do not yet know positively what the substances are which, interposed between silver and platinum and gold wires, give rise to the loose-contact currents, but I feel no doubt that these are as much thermo-electric currents as those given by the oxides of copper and iron, and are produced in a circuit composed of the metal and a very thin hot film, of which the two surfaces are unequally heated.

There are, however, some good reasons for doubting whether electrolytes can be included in a true thermo-electric series, and I consulted many authorities with reference to this point. Seebeck himself includes many electrolytes in his thermo-electric scale, and places acids below bismuth, a result confirmed lately by Gore (in 1857); he also places certain salts above antimony, a result subsequently confirmed by Andrews of Belfast in 1837. This gentleman observed that the tension produced by the salts between the wires was about equal to that between a platinum and silver plate in dilute sulphuric acid, and that the metals used as electrodes did not influence the deflection. He considered the current certainly due to a thermo-electric action.

Faraday in 1833 discovered what Becquerel subsequently called pyro-electric currents; the currents were in different directions with different substances used, and some, if not all, were of the same nature as those I have described. Leroux and Buff obtained currents where glass acted as the electrolyte. Leroux considered them thermo-electric, and Buff chemical effects. Buff also attributes some of the electrical phenomena connected with flame to a thermo-electric action in which unequally heated air or gas forms part of the circuit. The currents obtained when a hot and cold platinum wire are dipped into dilute sulphuric acid and other liquids are well known; and finally (in 1858), Mr. Wild published a laborious research, in which he seems to prove the development of thermo-electric currents not only at the junction between metals and various solutions, but also between two different solutions. Thus, although none of the above observers seem to have tested the oxides, there seems little reason to doubt that they may be classed with other electrolytes, and may give rise to currents in the same manner. On the other hand, I cannot yet consider it definitively proved that any of the currents obtained from electrolytes are due to a true thermo-electric action—that is to say, to an absorption of heat only, especially as Mr. Wild could find no trace of the Peltier heating and cooling effect at the junctions of his solutions. Further research, showing the source of the power developed, is most desirable.

While consulting the literature connected with this subject, I found that Gaugain had to some extent preceded me in the discovery of the loose-contact currents, in a paper published in the *Comptes Rendus*, in 1853. He comes to the same conclusion as I had done independently, that they were due to the unequally heated film of foreign matter, and places oxide of iron below platinum, and oxide of copper above gold and zinc, but below iron, instead of very much above it as I find. He does not appear to have observed the exceedingly high electromotive force to be obtained from these bodies, no doubt owing to the use of a short galvanometer coil of thick wires, such as is commonly used for thermo-electric researches. He introduces a carburet of iron, of which I find no trace, with more positive properties than oxide of copper, to explain some of his results. He gives very few data on which to found his theory, but simply mentions his conclusions, and appears to have made no direct experiment whatever with the oxides. Owing to these circumstances his experiments seem to have attracted little attention. I have endeavoured to contrive a convenient apparatus by which to study the properties of the oxides, but have not hitherto met with much success, owing to the great difficulty in maintaining a constant difference of temperature between the surfaces of the very thin film, which can alone be used with success. Next year I hope to obtain further results in elucidation of these quasi thermo-electric currents from electrolytes.

I now wish to add a few remarks on the currents which occur when true metallic contact is made between a hot and cold end of a wire of one metal. The existence of these currents was placed beyond all doubt by Magnus's careful experiments, but their connection with other thermo-electric phenomena has hitherto remained entirely without explanation. Wild has suggested that they might be due to a thermo-electric couple formed with hot air or gas at the moment of junction; but experiments which I have made show this explanation to be founded on a mistaken conception of the duration of the current, which is by no means instantaneous, but lasts at least five minutes with copper or with iron wires, very gradually decreasing in intensity from a maximum to zero.

Another explanation, viz. that the deflection is due to a sort of discharge of a statical effect produced by the unequal distribution of heat, is also negatived by the same consideration, as well as by the fact that a tension of sufficient magnitude to produce such a charge could not possibly have escaped observation by direct measurement.

Professor W. Thomson has shown conclusively, in his *Dynamic Theory of Heat*, that if the condition of metal at a certain temperature depended exclusively on that temperature, no distribution or movement of heat could possibly give rise to a current of electricity in a circuit of one metal; nevertheless I find, as above stated, that in a circuit of one metal wire a current is maintained for five minutes at a time, gradually vanishing to nothing when the two ends of the homogeneous wire have been for some time in contact, but recommencing if one wire is cooled for a minute and then again applied to the hot one. One explanation of this might be that the condition of the wires does not solely depend on their temperature, but is influenced to a considerable extent by the time during which they have remained at that temperature. Nor is this a gratuitous assumption: Dr. Matthiessen has proved that wires of several metals do not attain a constant *conducting* power until they have been kept for some time at a constant temperature; he finds that the conducting power of bismuth increases, while that of tellurium decreases when kept for a time at 100°. Quite similarly, some metals may rise and some may fall in the thermo-electric scale after being heated for some time, a supposition which is necessary to account for the metallic contact currents by the theory I suggest.

Another possible explanation of the metallic contact currents may be found in a partial hardening on the one side and annealing on the other, caused by the sudden contact of the hot and cold metal. If this be so, the current between annealed and unannealed wires of the same metal would correspond with the contact current between two homogeneous wires, in a way which it does not seem to do.

I am, however, now engaged in investigating this subject, and hope before next year to be able to give facts which may decide whether either of these theories is tenable. There is great difficulty in forming any conclusion from experiments hitherto made, inasmuch as none of the observers, except Dr. Matthiessen, have used chemically pure metal, and it is found that the electrical properties of a metal are affected to an extraordinary degree by the presence of impurities in very small quantities.

CORRESPONDENCE.

TELEGRAPHIC FAC-SIMILES.

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—"Veritas" claims for Mr. Alexander Bain the merit of being the inventor of the system of telegraphing introduced by Bakewell and others. Mr. Bain was unquestionably a most ingenious mechanician; but was he the inventor of the electro-chemical telegraph upon which is based Bakewell, Bonelli, Casselli, and others? In 1840 it appears that a Mr. R. Smith, of Blackford, Scotland, invented an electro-chemical telegraph similar in every respect to that subsequently patented by Mr. Alexander Bain. In Mr. Smith's instrument a strip of cloth, saturated with a solution of ferrocyanate of potash, &c., was made to pass over a brass roller put in motion by clockwork. When the apparatus was ready for signalling, the pressing down of the key formed the connection, and a blue mark was printed upon the cloth, by the electric fluid decomposing the ferrocyanate of potash, communication being carried on by a series of dots and lines. The electro-chemical telegraph of Mr. Bain was in extensive use both in England and America at one time, but is now almost entirely superseded by the Morse intrument, and I believe that the Morse must sooner or later give way to the Hughes and the Bonelli instruments, from the great rapidity by which communication can be transmitted by means of those instruments.

Scotia. I am, &c., ALEXANDER.

THE ATLANTIC TELEGRAPH COMPANY.

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—The determination of the Atlantic Telegraph Company to carry out the great project, in the success of which the civilized world is so deeply concerned, cannot be too highly applauded. I trust that now, as the determination is formed, and that the cable is in course of manufacture, we shall have a truce between rival contractors and patentees. Telegraphy has suffered grievously from the discordant elements by which it has too long been surrounded and trammelled. Let us hope now that "good times are coming." There is a wide field for enterprise. We shall require many Atlantic cables to supply the commercial requirements of the vast continents sought to be united; therefore, let obstructive rivalry cease. There is ample room for all. A LOVER OF PROGRESS.

TELEGRAPHING WITHOUT WIRES.

To the Editor of the TELEGRAPHIC JOURNAL.

Sir,—In the *Telegraphic Journal* of the 14th of March, in reply to your correspondent, "A Reader," a quotation is inserted from the specification of a patent granted to Mr. Haworth for a mode of telegraphing without wires. The subject has been often brought before the public during the last two years, and has even, if I am correctly informed, created quite a sensation amongst those whose good fortune it is to have the control of the national purse, and who, believing in the practicability of the invention, have declined to render any assistance to the great project of an Atlantic telegraph, which is now in a fair way of being realized, thanks to the liberality and discernment of an enterprising public. It appears to me incomprehensible, after the achievements attained as alleged in the specification, that no further progress has been made to render the discovery available for the purpose of telegraphic communication. Surely an apparatus capable of transmitting messages between Notting Hill and Bangor in North Wales, would be most advantageously employed, as the rapid extension of the expensive old system proves that the community fully appreciates the benefits of instantaneous means of communication. As there are numerous projects on foot for extending the advantages of international telegraphy, I hope that Mr. Haworth and his friends will no longer keep back, as it were, so valuable a discovery, but that steps will be taken at once to put it to a practical test in the presence of competent persons. Many efforts have been made from time to time to communicate by electricity without the aid of metallic conductors, but without any practical results, and I am afraid that in the present instance it will be "hope deferred," which "maketh the heart sick." Yours, &c.,

A. M. P——L.

BRITANNIA RULING THE WAVES.—This extraordinary feat may be witnessed any day by repairing to any of our submarine telegraph offices, when the whole process of ruling will be shown to the stranger. At present Britannia only rules the waves with a few lines; but in a short time it is expected she will become so perfect as to rule it with some hundreds of lines. In fact, it is considered that the ocean eventually will be nothing but an immense copybook which Britannia will be continually ruling, the better to enable historians to write her proud achievements upon it, as well as assist her in corresponding with other nations in all the gentle terms of peace and fellowship. May science, as in this instance, guide Britannia's hand in ruling the waves!

TELEGRAPHIC NEWS.

Government Returns.—In the miscellaneous estimates for last year there is an item of £280 for the erection of a line of telegraph to Balmoral.

New Public Enterprises.—We are pleased to find that the shares of the Bonelli Electric Telegraph Company and Silver's India Rubber and Telegraphic Cable Company are already at 1½ to 2 premium.

Indo-European Telegraph.—The last steamers of the Persian Gulf telegraph expedition have left Bombay for Cape Mussendum.

Bonelli Telegraph Company.—We are glad to understand that D. J. Jaffé, Esq., of Belfast and Hamburg, has joined the Board of Directors of the Bonelli Telegraph Company. We believe that the Company will be in a position to commence business, at latest within six months from the present day, between the principal towns in England.

Toulon and Ajaccio Submarine Cable.—Advices from Toulon of the 2nd inst. state that, in consequence of the impossibility of repairing the submarine cable between Toulon and Ajaccio, it is intended to undertake the laying of a cable between Nice and Calvi.

Gisborne's Signalling Apparatus.—We quote the following from the *Times*, of the 4th instant:—The Lords of the Admiralty have given directions for Gisborne's electric engine-room telegraph to be fitted on board the iron frigate Achilles, at Chatham, the report of the working of the apparatus on board the Royal Oak, in which vessel it was fitted, having been exceedingly satisfactory. The inventor is also to fix a mechanical telegraph from the engine-room platform to each of the stoke-holes.

Telegraph Engineering.—Those of our readers who are in the habit of travelling on the North London Railway between Fenchurch-street and Chalk Farm must have observed with pleasure the new standards and insulators and wires recently erected along a portion of that line. The standards have a very handsome appearance, and are painted in a light and cheerful green, and the insulating arrangements are of superior description; in every respect the work has been admirably executed.

The Great Eastern and the Atlantic Cable.—The steamship Great Eastern has been taken up by Messrs. Glass, Elliot, & Co., the contractors for the Atlantic cable, for the purpose of laying it between England and America. The Great Eastern will be handed over to the contractors on the 1st of May, who from that date pay all the expenses of the steamer, including wages, victualling, insurance, &c., and when the cable is laid the proprietors of the Great Eastern are to receive £50,000 in paid up shares of the Atlantic Telegraph Company. Although Messrs. Glass, Elliot, & Co. take possession of the steamer on the 1st of May, it is not their intention to lay the cable across the Atlantic till next spring.

Telegraph Construction and Maintenance Company, Limited.—This company has been formed for the purpose of carrying on under one management the combined business of the Gutta Percha Company and that of Messrs. Glass, Elliot, & Co., and it is presumed that the union of the two establishments will be of the most beneficial description. Whilst Messrs. Glass, Elliot & Co. have had to lay the principal portion of the submarine cables, the Gutta Percha Company, on the other hand, have had the manufacture of the cores. The capital proposed is £1,000,000, in shares of £20 each, the first issue to be 37,500 shares, representing £750,000, and the board of directors is such as cannot fail to ensure perfect confidence in the undertaking. The services of Messrs. Barclay and Glass have been secured as managing directors, who will be assisted by the staff of the united establishments; and from the high reputation gained by Messrs. Glass, Elliot, & Co., and the extensive business of the Gutta Percha Company, the investment cannot fail in realizing large profits. With the consent of the Treasury, the lease of the Malta and Alexandria line, held by Messrs. Glass, Elliot, & Co., will be transferred to this company, as will also the Alexandria, Cairo, and Suez Telegraph.

Atlantic Telegraph Company.—The following communication has been addressed to the existing shareholders in the company:—"Atlantic Telegraph Company, 22, Old Broad-street, E.C., London, April 2, 1864.—Sir,—I am instructed by the directors to inform you that the submarine electric telegraph cable for connecting Europe with America during 1865 is now in course of construction under a contract with Messrs. Glass, Elliot, & Co., the particulars of which were sanctioned by the shareholders at an Extraordinary Meeting held on the 31st ult. Under that contract the Company undertake to deliver to the contractors in cash during the construction of the cable the sum of £350,000, the remainder of the cost being payable in shares and bonds of the Atlantic Telegraph Company. The 8 per cent. preferential capital subscribed for and paid upon at present is £306,000, leaving £44,000 in 8800 shares of £5 each to be taken up. In the allotment of these 8800 shares, priority will be given to existing shareholders whose applications are received at this office on or before Saturday, the 9th instant.—I am, dear sir, yours truly, Geo. Saward, *Secretary*.

The Euphrates Telegraph.—Our last notice of the laying down of the telegraphic cable which is to put England and India in communication, through the Persian Gulf, left the cable at Ras Mundanny, on the Mekran coast. The splice between the end of the piece of cable on board the Kirkham, and the beginning of that on board the Marian Moore, had just been completed, and all the vessels were ready to start again on the morning of the 6th instant, when it was discovered that one of the principal members of Colonel Stewart's staff was missing; this was Dr. Ernest Esselbach, a gentleman of great eminence in the scientific world, who had been selected for the very important office of chief superintendent of the line when completed; the circumstances under which he disappeared, and a letter which he left behind him, made it almost certain that he had committed suicide by throwing himself overboard. Two days previously he had shown sudden symptoms of mental disorder, and having conceived an unconquerable aversion to the vessel in which he was at the time, he was transferred to another, being accompanied by a friend to whom he was much attached. On the second day after his removal he seemed so much better that his friend had hopes that the deep melancholy into which he had fallen was passing off; but he was mistaken; for (as was afterwards discovered) at that very time the unfortunate man was making preparations for a sudden termination of his life, which there is no doubt took place by his own act during the night of the 5th of February. His death is a real loss to the Indo-European telegraph, for what he had already done to improve the practical application of the branch of science to which he had chiefly devoted himself was looked upon as a guarantee that, under his management, this, the most important telegraph in the world, would be the most perfect also. The steamers got up steam, and about eleven A.M. the Coromandel started ahead to show the way, followed by the Zenobia towing the Marian Moore, which paid out the cable as she went along. On the following morning the squadron was off Cape Jask, a promontory on the Persian coast of the Gulf of 'Oman. Hitherto the cable had been laid parallel to the shore, and generally in depths of which about thirty fathoms would be the mean; but at this point it had to be carried across the mouth of the Gulf of 'Oman to Ras Mussendum, a rocky promontory which runs out in a north-easterly direction from the south-east end of Arabia, and divides the Persian Gulf from that of 'Oman. As a straight line from Cape Jask to the Persian Gulf must pass across Ras Mussendum, there is, of course, a saving in carrying the telegraph wire over it, instead of round by the extremity of the promontory; but as a submarine cable is considered much safer in these wild districts than a land line, it was desirable to find the narrowest part; this is a ridge of rock, about half a mile wide, which separates Malcolm's Inlet, on the Gulf of 'Oman side, from Elphinstone Inlet, on the Persian Gulf side. Accordingly, the vessels made for the mouth of Malcolm's Inlet, the Victoria and Coromandel leading the way for the Zenobia and Marian Moore, which passed after them to the head of the inlet, both gaily dressed with flags in honour of the perfectly successful accomplishment of so much of this undertaking. Malcolm's Inlet presents most striking natural features; it is a long, deep, winding and branching indentation into a rocky coast, extending in for several miles from the sea, and ending in a spacious rocky basin, with deep water on every side, so that large ships can anchor almost within a stone's throw of the shore, while the black rocks tower above it, at some points to a height of four or five thousand feet. The Imaum of Muscat claims sovereignty over this barren region, and Colonel Disbrowne, the political resident at Muscat, had already obtained his permission for the passage of the telegraph wire across the neck of land, and the establishment of a repeating station on it; but, after all, it seems very doubtful whose territories this barren spot is in, even the inhabitants do not seem to know, some speaking of a Sheik named Ben Suggar of Rassal Keemar as their rightful ruler, while others look upon the head men of their villages as "without superiors on earth," and responsible to God alone! The Arabs soon began to flock off to the ships in very original looking boats, and became most pressing and troublesome in their familiarities, but, as it was most important to secure their good-will for the sake of the electricians, signallers, and others who were to be left on shore in charge of the repeating station, they were treated with the utmost kindness, and no effort was spared to propitiate them by presents of rice, sugar, coffee, &c. Evidently they do not understand *quid pro quo*, for when asked to assist in landing stores, pitching tents, and building one or two wooden huts, and though promised liberal payment in money or food for doing so, they showed no alacrity to close with the offer. The greater part of the stones for the station have to be conveyed by the native crews of the ships up a most difficult hill; the labour is immense, and the assistance of two or three hundred Arabs would be most valuable, but they are very slow in giving it, and when they do, they do not work with a will. The old plan of paying a few rogues well to watch the rest has succeeded perfectly hitherto, the charge of all the stores landed having been entrusted to about a dozen Arabs. Colonels Stewart, Disbrowne, and Goldsmid have all had great experience in dealing with wild tribes, and the policy they think best is to secure the good-will of the leading men, by making it their interest to treat our people well; the greatest difficulty they have is to find out who are the real chiefs, for the local politics are most intricate, and every now and then the knots into which they get are so complicated, that the sword is deemed the only means of solution; the natural result is jealousy and hatred between the nearest neighbours, a state of matters which often impedes the arrangements necessary for the success of the telegraph, and calls for the most delicate management. Provisions of all kinds are exceedingly scarce at this place, and what is worse, good water can only be obtained from a distance; these wants greatly increase the difficulties in the way of establishing a station here; indeed, nothing but the determined energy of Lieut.-Colonel Stewart, aided by Mr. Walton, with valuable assistance from all the Bombay marine vessels, could have overcome them. Colonel Stewart never spares himself any fatigue of mind or body, though his health is far from good; indeed, his

friends (and every one of the party feels the interest of a friend in him) are constantly obliged to urge upon him the necessity of sparing himself, which he is never willing to do, even though he knows the necessity. But to return to the actual laying of the cable. It went on at an average rate of about five knots an hour throughout the whole 360 miles from Guadur to Mussendum. Sir Charles Bright says that he scarcely ever before knew so long a piece laid down as this has been, without the slightest hitch or accident of any sort; the complete success of all the mechanical arrangements is almost more than could have been certainly counted upon, as this is the first time that a long stretch of cable has been paid out of ships in tow, the moving power having always hitherto been on board the same ship as the cable; in carrying out the present plan, one great desideratum was to devise a means of communication between the towed and the towing ship, and this has been most successfully accomplished by an ingenious application of the telegraphic alphabet; the plan is most simple, though it requires considerable practice in those who use it. By day, conversation is carried on merely by movements of the hand, or of a pocket-handkerchief; at night, by alternately showing and concealing a single bright light; in this manner persons in different ships can talk almost as rapidly, and quite as fully, as if standing side by side; but of course much of the success of this means of communication depends, in a case like the present, on those in the steamer being constantly on the alert for signals from the cable ship. Sir Charles Bright gives Lieutenant Carpendale and the officers of the Zenobia—the vessel which had both the cable ships in tow during the time they were paying out—very high praise for the speed and celerity with which every one of his signals was attended to. It is quite evident that the laying down of submarine cables has become a distinct branch of engineering, and that Sir Charles Bright and his staff are thorough masters of every detail. So far as the work has gone, it may be pronounced a complete success; communication between Bombay and the farthest end of the cable is uninterrupted, and much important business connected with the expedition is daily transacted through it. If things only go on as they have begun, less than three months will see messages passing, with almost electrical speed, from London to Calcutta; we say, almost, for the recent disturbances among the Arabs in Mesopotamia, when they ill used some Europeans connected with the work, will probably render it necessary, for a time, to employ messengers across part of that district, though there is every reason to hope that next year all difficulties, even in that wild region, may be got over by negotiation. When the Bombay marine steamer Victoria left, Colonel Stewart with his staff, Sir Charles Bright, and Colonel Goldsmid, were just about making a hurried trip in the Coromandel to Bushire and Bussorah, to make arrangements for the stations to be established at those points, and to facilitate the arrangements in Mesopotamia. By the time they return to Mussendum, they will probably find the Tweed and Assaye with further sections of the cable awaiting them. If so, and the weather be even tolerably favourable, ten days would see the end of the cable in the Euphrates.—*Times of India, 14th March.*

MISCELLANEA.

THE EARLY DAYS OF TELEGRAPHY.—One of the most striking proofs of the power of the telegraph was given, almost in its infancy, by the capture of the murderer Tawell; and as it is so graphically described by the talented author of the *Bubbles from the Brunnens of Nassau*, in an interesting and instructive work styled *Stokers and Pokers*, we cannot do better than transcribe it here:—"He never expected that! He had made up his mind to give her the stuff—he had deliberately bought it—had paid for it—had put it into his pocket—had driven with it to the terminus of the Great Western Railway—had flown with it along the line to Slough—had walked with it to the cottage. He had already deprived the poor creature of her character, and now, on the first day of the year 1845, he had come down to her on purpose to deprive her of her life. With affected kindness he had offered her refreshment—had waited while, with his money, she went to buy it—he had summoned up courage?—no, cowardice and wickedness enough, secretly to pour the stuff from a tiny phial into her glass—he had seen her, with feelings of gratitude to him, raise the mixture to her faded lips—he had watched her swallow the first mouthful—then another—then drink. He had expected every instant, as she reached the drugs, to see his degraded victim drop down dead before his eyes; he could bear all this, but he did not know that it was the nature of the horrid poison he had purchased to betray the hand that administered it. Oh! he never expected that loud, horrid, piercing convulsive scream! As, terrified and scared, he opened the door to escape, the inhabitants of the neighbouring cottages, alarmed by the frightful noise they had just heard, sympathetically opened theirs. They saw him leave the house with hurried steps, observed him make for the Slough-road, where, by another party, he was observed to be 'confused, to tremble, and, on being addressed, to make no reply.' And yet he had only done what he had deliberately intended to perpetrate. He knew there was no rest for the wicked, but, oh! he had never expected that shrill, fearful haunting scream! On reaching the station, he took his place in a departing train, and in a few minutes he had, apparently, effected his escape. Everybody who has travelled by the Great Western Railway knows how joyously its well-appointed trains skim along the level country between Slough and London. He no doubt appreciated the speed, valued the wings with which he was flying more than any of his fellow-passengers. He probably felt that no power on earth could overtake him, and that if he could but dive into the mass of population in London, he would, in perfect security, flow with its streams unnoticed. But whatever may have been his fears, his hopes, his fancies, or his thoughts, there suddenly flashed along the wires of the Electric Telegraph, which were beside him, the following words:—'A murder has just been committed at Salthill, and the suspected murderer was seen to take a first-class ticket for London, by the train which left Slough at 7.42 p.m. He is in the garb of a quaker, with a brown great coat on, which reaches nearly down to his feet. He is in the last compartment of the second first-class carriage.' And yet, fast as these words flew like lightning past him, the information conveyed in them, with all its details, as well as every secret thought that had preceded them, had already consecutively flown millions of times faster; indeed, at the very instant that, within the walls of the little cottage at Slough, there had been uttered that dreadful scream, it had simultaneously reached the judgment-seat of Heaven! On arriving at the Paddington Station, after mingling with the crowd for some moments, he got into an omnibus, and as it rumbled along, taking up one passenger and putting down another, he probably felt that his identity was every minute becoming confused and confounded, by the interchange of fellow-passengers for strangers, that was constantly taking place. But all the while he was thinking, the cad of the omnibus, a policeman in disguise, knew that he held his victim like a rat in a cage. Without, however, apparently taking the slightest notice of him, he took one sixpence, gave change for a shilling, handed out this lady, stuffed in that one, until, arriving at the Bank, the guilty man, stooping as he walked towards the carriage door, descended the steps, paid his fare, crossed over to the Duke of Wellington's statue, where, pausing for a few moments, anxiously to gaze around him, he proceeded to the Jerusalem coffee-house, thence over London-bridge to the Leopard coffee-house, in the Borough, and finally, to a lodging house in Scott's-yard, Cannon-street. He probably fancied that by making so many turns and doubles, he had not only effectually puzzled all pursuit, but that his appearance at so many coffee-houses would assist him, if necessary, in proving an alibi; but, whatever may have been his motives or thoughts, he had scarcely entered the lodging when the policeman,—who, like a wolf, had followed him every step of the way,—opening his door, very calmly said to him,—the words, no doubt, were infinitely more appalling to him even than the scream which had been haunting him, 'Hav'n't you just come from Slough?' The monosyllable 'No,' confusedly uttered in reply, substantiated his guilt. The policeman made him his prisoner,—he was thrown into jail,—tried,—found guilty of wilful murder, and—hanged! A few months afterwards we happened to be travelling by rail from Paddington to Slough, in a carriage filled with people, all strangers to each other. Like English travellers, they were all mute. For nearly fifteen miles no one had uttered a single word, until a short-bodied, short-necked, short-nosed, exceedingly respectable-looking man, in the corner, fixing his eyes on the apparently fleeting posts and rails of the Electric Telegraph, significantly nodded to us as he muttered aloud, 'Them's the cords that hung John Tawell.'"

THE JOINT STOCK COMPANIES' ASSOCIATION (LIMITED), in 10,000 shares of £5 each, has just been projected. The object of this association is to organise and assist in bringing before the public, *bonâ fide* joint stock companies, the association receiving reasonable remuneration for so doing, whilst all schemes of a doubtful character as to their ultimate success will be carefully excluded. The delay attendant upon the formation of joint stock companies by private individuals will be avoided, the costs materially diminished, and a greater certainty of success attained. The company offer to undertake the duties of secretary, managers, and auditors of accounts, and provide office accommodation where it is needed, from which portion of their business they expect to derive considerable income. In the present *furore* for joint stock companies, many of which are of a very doubtful character, the guarantee of an association of this description, as to the soundness of the schemes brought forward, is very desirable; and when we see such names as Lord Henry Gordon, as chairman of the board, and Lord Kinsale as deputy-chairman, we cannot be far wrong in recommending the association to the notice of capitalists. We also notice the name of S. R. Bennett, Esq., of Nicholas-lane, on the direction, a gentleman whose large experience in matters of that description tends to give confidence in the efficient working of the company. A deposit of 10s. is to be paid upon application, and 10s. upon allotment, and no further call is expected to be required, and none is to be made within three months.

A POPULAR FALLACY.—It is a common error to suppose that birds are often killed by settling on the wires, and accounted for by the idea that they are struck down by the electric fluid passing through them. This is not possible, unless they touch two wires, and thus form a connecting medium, through which the electric current might pass. As they simply settle on the wire, the current continues on its way, preferring the metallic medium to that offered by the body of a bird. But if a bird had one leg on the wire and the other upon the ground, the electric fluid might be arrested in its course, and pass, through the body of the bird, into the ground; it is well known, and has been before mentioned, that electricity invariably takes the shortest route it can find, and it is, therefore, only reasonable to suppose that it would do so in the instance under consideration. In such a case,

if the electric current was of a sufficiently powerful nature, death would doubtless ensue, and the bird would present the appearance of having been killed by a stroke of lightning. Such an event is, however, not known in Great Britain, owing possibly to the fact that none of our birds possess legs eighteen feet long!—*Dodwell's Handbook.*

Character.—The crown and glory of life is character. It is the noblest possession of a man, constituting a rank in itself, and an estate in the general good-will; dignifying every station, and exalting every position in society. It exercises a greater power than wealth, and secures all the honour without the jealousies of fame. It carries with it an influence which always tells, for it is the result of proved honour, rectitude, and consistency—qualities which, perhaps more than any other, command the general confidence and respect of mankind. Character is human nature in its best form. It is moral order embodied in the individual. Men of character are not only the conscience of society, but in every well-governed State they are its best motive power; for it is moral qualities in the main which rule the world. Even in war, Napoleon said the moral is to the physical as ten to one. The strength, the industry, and the civilization of nations—all depend upon individual character; and the very foundations of civil security rest upon it. Laws and institutions are but its outgrowth. In the just balance of nature, individuals, and nations, and races, will obtain just as much as they deserve, and no more. And as effect finds its cause, so surely does quality of character amongst a people produce its befitting results.

Perseverance.—Much will be done if we but try. Nobody knows what he can do until he has tried; and few try their best until they have been forced to do it. "*If* I could do such and such a thing," sighs the desponding youth. But he will never *do*, if he only wishes. The desire must ripen into purpose and effort; and one energetic attempt is worth a thousand aspirations. Purposes, like eggs, unless they be hatched into action, will run into rottenness. It is these thorny "ifs"—the mutterings of impotence and despair—which so often hedge round the field of possibility, and prevent anything being done, or even attempted. "A difficulty," says Lord Lyndhurst, "is a thing to be overcome;" grapple with it at once; facility will come with practice, and strength and fortitude with repeated effort. Thus the mind and character may be trained to an almost perfect discipline, to enable it to move with grace, spirit, and liberty, almost incomprehensible to those who have not passed through a similar experience.

Secrecy of Telegraphic Communications.—Although the electric telegraph has been in successful operation in this country for sixteen years, scarcely an instance is on record where the secrecy of a despatch has been violated. This is owing mainly to the high sense of honour which every operator feels upon this point, there being no oath of secrecy required, and no laws for the punishment of its violation; but there is another circumstance which, as experience has made manifest, has given security to the public on this point. It appears that the operators who are for many hours labouring at the instrument in the transmission of despatches, word by word, rarely are able to give that kind of attention to the sense and purport of the whole which would be necessary to the clear understanding of it. Their attention is engrossed exclusively in the manipulation necessary to transmit letter after letter, and they have neither time nor attention to spare for the subject of the whole despatch. The case is very analogous to that of compositors in a printing-office, who, as is well known, may go through their work mechanically, without giving the least attention to the subject.—*Prescott.*

Jointing India-Rubber and Percha.—The weakest portion of every piece of "covered work" is the joints. The following are the instructions given by the Gutta-Percha Company:—"Have in readiness a few strips, about ⅝ inch broad, of very thin gutta-percha sheet, also a little warm gutta-percha, about ⅛ inch thick, one or two hot tools, and a spirit lamp. Remove the gutta-percha covering from along the wire no further than may be necessary for making the joint in the wire. Having joined the wire, warm gently with the spirit lamp the bare wire and joint, and the gutta-percha near to it. Taper the gutta-percha over the bare wire until the ends meet; warm this and immediately apply one of the strips of thin sheet in a spiral direction over it. Press this covering well on until cool, then, with the spirit lamp, carefully warm the surface and proceed as before to put on a second strip of the thin sheet, observing to wrap it in a direction reverse from the first strip, always making the commencement and termination of these coverings to overwrap the previous one. It is safer to perform this operation a third time. Next, take a piece of the warm ⅛ inch sheet and cover over the coats of thin sheet, again overwrapping the original covering of gutta-percha, which should be heated so as to ensure perfect adhesion. Press it well on as it cools, and when cold, or nearly so, finish off the joint with a warm tool, working well together the old and new material at each end. Lastly, and in general, avoid moisture, grease, or dirt, and be careful not to burn the gutta-percha, which would prevent proper adhesion. It is well to clean and soften the surface of the percha with rectified coal naptha. Cleanliness is most essential to success. The fingers should be used as little as possible, and must be kept very clean. The kneading and finishing the joint should be performed with the tools provided for that purpose. Moisture, tar, dirt, and grease, are fatal to a joint. The thin strips must be kept clean and dry in a small box." Rubber joints are made in the same way as percha, except that heat is not used, and that the strips are well moistened with rectified coal naphtha. It is well to cover percha joints with a layer of rubber. No one but the lineman in charge of the work, who will have the trouble of repairing it if defective, should be entrusted with the delicate operation of making joints.

TO CORRESPONDENTS.

As information respecting Improvements, Extension of Lines, and Progress of New Undertakings will at all times be most acceptable, we hope that our readers will kindly render us assistance in our efforts to establish a Journal worthy in all respects of the great interest it seeks to represent, by furnishing us with brief notices of events and occurrences in connection with Telegraphy.

Communications intended for publication must be authenticated by the names and addresses of the writers; not neccessarily for insertion.

Letters relating to Advertisements are to be addressed to the Publishers. All other letters and communications to be addressed to the Editor of the *Telegraphic Journal*, 5, Suffolk-lane, Cannon-street, London, E.C.

The *Telegraphic Journal* can be had of Messrs. Smith & Co., Strand; Messrs. Dawson & Co., Cannon-street, E.C.; Messrs. Kent & Co., Paternoster-row, London. Messrs. Heywood & Co., Manchester; at the various railway stations; and of all news-agents, &c., &c.; or it can be supplied, if preferred, direct from the Office on the following terms;—

	s.	d.
Quarterly	4	4
Half-yearly	8	6
Yearly	17	4

TO ADVERTISERS.

The *Telegraphic Journal* is the most effective medium for inventors, patentees, contractors, manufacturers of insulating materials and electrical apparatus to submit their various specialities to the consideration of secretaries and managers of telegraph or railway companies, and other persons engaged in electrical and telegraphic pursuits.

Clerks, assistants, manipulators, and instrument makers, seeking employment, &c., will find the *Telegraphic Journal* a ready means of making known their requirements.

Advertisements must be delivered to ensure insertion before Seven o'Clock on Thursday evening in each week. The charges for Advertisements are—

	£.	s.	d.
Whole page	4	4	0
Half ditto	2	10	0
Quarter ditto	1	7	6
Four lines and under (single column)	0	3	0

Single Advertisements from the country must be accompanied with stamps in payment.

ON THE APPLICATION OF ELECTRICITY TO DOMESTIC PURPOSES.

By WILLIAM HENRY PREECE, Assoc. Inst. C.E.

THE application of electricity to all kinds of national, public, and social purposes, has rendered it one of the most interesting and useful studies of the day. It is used not only to transmit our thoughts and wishes to distant lands, but to guide our ships through the stormy ocean, to protect our lives in the whirling train, to beautify our table utensils, to ornament our articles of daily use, to copy our finest engravings, to illuminate our light-houses, to alleviate pain and to cure disease; and now it promises to become one of the most useful additions to the comfort and proper regulation of our hearths and homes. The domestic electric bell has every appearance of becoming generally adopted. It is so cheap and so perfect, so easily regulated, and so simply fixed. It obviates the evils of the existing system, and introduces points of great originality and advantage. Its merits have but to be known to secure its speedy adoption. It is intended in the following paper to draw a comparison between the present domestic and the electric bell, to enunciate the principles upon which the latter is based, and to describe its construction and working.

The use of bells for the purpose of attracting attention is of very ancient date. We find them in use amongst the early Jews, Greeks, Romans, and Christians. But they were chiefly employed for religious and military purposes,—suspended in churches, temples, or monasteries, to summon devotees to their religious ceremonies, or elevated in camps and frontier towns to alarm the garrison in cases of surprise or attack. The hour of bathing among the Romans was announced by a bell, and it was fastened to the necks of cattle that they might be traced when they strayed—a practice in vogue even at the present day. The Jewish priests were directed by Moses to employ them fixed to their robes.

Their employment for domestic purposes is, however, of more modern date. Subsequent to their introduction, in all large houses a domestic was in constant attendance near the principal sitting-room, whose attention was called by a clap of the hand, a stamp of the foot, or by one of the well-known Shakespearian calls:—

"What ho!"—"Without there!" or "Who waits?"

The use of the hand is still practised in the East to attract the attention of the attendant slave, but in civilised countries the modern bell has superseded all other contrivances. The first form which the domestic bell took was that of a small circular bell, or metal disc, fitted on a tall, ornamental leg, and placed upon the table. It was sounded by striking it with a piece of hard wood, cane, or metal. The ordinary hand-bell, with the moveable clapper, which is so well known in the hands of the muffin-man, was subsequently introduced. A hand-bell is still frequently in use in offices and occasional quarters, which is sounded by the pressure of the hand; a knob is depressed, which releases a spring, that drives a hammer with much force against the bell. The hand-bell, however, still necessitated the attendance of a servant, as its sound could not reach the servants' hall or butler's pantry. A great advancement was, however, made in the introduction of the bell-pull. By means of wire cranks and levers, bells could be fixed in any part of the house, and be rung from any room. Such bells are now in general use. The peer's palace and the poor man's cottage are equally supplied with them. They are as much an article of household use as a fireplace or a table. A few yards of copper wire, led underneath the flooring, through the ceiling, down the walls, and along the passage, with two or three cranks to convert the straight pull into any altered direction, and a bell can be sounded anywhere.

There is, however, a limit to the distance at which a bell can be rung. If it be too far off the strain required is such that the wire stretches and becomes useless. Again, passing underneath floors, and through exposed crannies, the cranks become clothed with dust and dirt, and therefore stick. Being constantly under a strain, the wire is not only liable to elongate, but the fixed parts and plugs are constantly liable to shift. So many parts of the apparatus are moveable. Rats and mice heap up dirt over the instable parts of the wire, and render them fixtures. We all know the disagreeable sound made in one room by the ringing of a bell in the next, and in a small house when a bell-handle is even gently pulled this grating sound is heard in every other room. Each particular room requires a different toned bell to distinguish it, and it becomes a great tax upon a servant's memory, particularly if she have not a musical ear, to recollect all the different notes. This evil is to some extent remedied by supplying the bells with levers, which continue to rock for some time after the bell has ceased to ring; this, however, at best, is but a clumsy contrivance. Indeed, every householder knows that, as at present constructed, bells are a constant source of trouble. The larger the house the more is this experienced, and in some of our palatial residences the bell-hanger is never out of the house.

It is evident, therefore, that some improvement is needed in the construction and working of our household bells. The chief cause of the inconvenience we suffer lies in the fact that we have to exert a strain upon the wire to produce a sound upon the bell. Remove the necessity of pulling the wire, the wire remains firm, the noise ceases, the cranks are abandoned, and it matters not how much dirt vermin heap over the wire—they can't eat it. All these evils—unpleasant noise, liability to stick, proneness to stretching, instability of parts, variation in tones—are entirely removed in the new electric bell, which is so extensively employed in France. Nothing struck me, in a recent journey to Paris, so much as the extensive use which our neighbours make of this new application of that wonderful science which serves our public and private wants to such a marvellous extent. Electric bells are used everywhere—in private houses, in public institutions, in merchants' offices, in ordinary shops, in cafés, and restaurants; all the large hotels—the Grand Hotel, the Louvre—are most completely provided with them; indeed, they have become a general domestic necessity. Enormous posters, as extensive as those of "Bel Demonio," "Leah," or "Miles' cheap trousers," upon our metropolitan walls, advertise them to the Parisian public. Large shops are devoted to their supply alone. They must, sooner or later, be introduced into England, for we can't long remain behind our neighbours across the water in an article of such advanced principles and of such domestic and every-day use.

A gentle pressure upon a small button effects all that is required. The electric force that rings the bell steals noiselessly along the wire, there is no sound, there is no strain; but the bell gives forth its warning sound as though it were rung by the stout arm of some invisible sprite.

How is this effected? We require a *battery* to generate the electric force, *wires* to convey it to the bells, *buttons* to bring it into play, *bells* to be sounded, and *tablets* to indicate the room from whence the impulse emanated. Let us consider them in order:—

1. *The Battery.*—The electricity employed is that usually termed "voltaic electricity;" it is the result of chemical decomposition, and is produced by the action of a galvanic battery. If we take a strip of zinc, Z (Fig. 1), and a piece of copper, C,

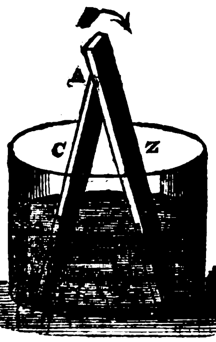

Fig. 1.

and place them in a vessel containing water, so that the submerged portions may be separated, whilst the upper parts rest against each other, we have a simple battery. The oxygen of the water attacks the zinc, chemical decomposition sets in, and a current of electricity is generated. This happens when the upper parts of the metals are placed in contact, but the moment they are separated all electrical action ceases. It matters not whether the metals are brought into immediate contact; a piece of wire connecting them would have the same effect. Such a battery as the above is of very weak and momentary power. The zinc becomes coated with oxide of zinc, which is insoluble in water, and stops all chemical action, and therefore all electrical generation. A little sulphuric acid, however, added to the water, obviates this by converting the oxide of zinc into sulphate of zinc, which is soluble in water, leaving the zinc clean, and allowing the chemical action to continue. As long, therefore, as there remains any zinc to be eaten away, and any sulphuric acid to unite with the oxide formed, a current will continue to flow until the solution becomes saturated with sulphate of zinc, when, by a peculiar electrical process, the metal zinc becomes deposited upon the copper plate, and stops all further action. To obviate this it is usual to place the zinc in a solution of sulphate of zinc, and the copper in a solution of sulphate of copper, separating the two by a porous earthenware partition, in which case copper, instead of zinc, is deposited upon the copper plate, which, of course, does not interfere with the generation of electricity.* Such a battery as this, with only one pair of plates, possesses but small power; it can only work through a very short distance, and gives but a feeble sound upon a bell. Any addition to the length of the connecting wire tends to reduce its power, but by increasing the number and size of the cells we can make it of sufficient strength to sound the loudest bell through the greatest distance.

Thus, let us take another vessel, with another pair of plates, similar to those employed in Fig. 1, and let the vessel be charged as in the previous experiment. Connect the zinc (Z) of the one to the copper (C) of the other by aid of the copper wires (A B), as in Fig 2. We now obtain a battery of double the power of

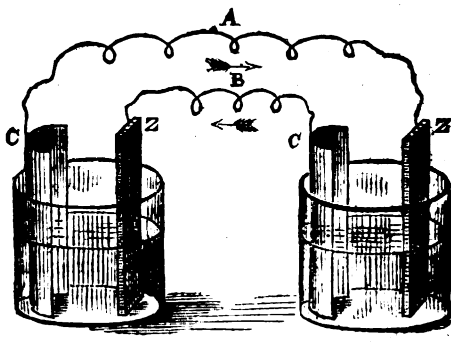

Fig. 2.

that in Fig. 1. By adding another cell, charged, and connected in the same way, we again increase the power, and so on by every additional cell we obtain additional power. The copper end (C) is called the positive (+), and the zinc end (Z) the negative (—) pole of the battery.

So long as the cells are connected by the wires A and B, the current generated will continue to flow as indicated by the arrows; but if the wire be broken or disconnected, or one of the plates be withdrawn, the current will cease. The wire, or "circuit," as it is technically termed, must be complete and unbroken before a current can pass. The current is always supposed to flow from the zinc through the liquid to the copper, and thence by means of the connecting wires back to the zinc. This flowing of the current is simply an arbitrary method of conceiving its action, and though probably not theoretically correct, it is practically the most useful method of describing the force generated by the battery. It does not imply the actual passage of any fluid or gas, but a simple transfer of force: an action which is progressive in its nature, like the passage of light through space, sound through air, or heat through a rod of metal.

As it would be excessively inconvenient, in practice, to employ a number of cells, as before described, to overcome the effects of resistance,* a more compact and convenient battery has been designed. It is a trough, made of teak, divided into a number of compartments, each compartment or cell answering the purpose of the vessel employed by us in Figs. 1 and 2. These cells, which are made water-tight with a lining of marine glue, are again divided by porous partitions, so as to keep the copper solution separated from that of the zinc. A plan of the battery in question is shown in Fig. 4. It is called a 12-plate *sulphate* battery, there being sufficient cells to accommodate twelve pairs of battery plates. It is charged by filling the zinc cell with water, or a weak solution of sulphate of zinc, and the copper cell with a solution of sulphate of copper, or with water and crystals of sulphate of copper. When the plates are laid in as shown, and the two poles C Z connected, we have battery power of sufficient influence to ring any bell that may be required for domestic purposes. The porous cells are shown as fixtures, but they are sometimes made moveable. Such a battery will retain its power for a considerable time without attention—ordinarily from six to eight months. It will then however give symptoms of impaired power.

The failure, or diminished action of the battery, is at once

* There are several secondary actions in the battery obviated or modified by this arrangement, but I have not considered it necessary to allude to them in these few elementary remarks. They will be found fully described in electrical works. My description of the action of the battery, also, will not bear theoretical analysis, but it has the merit of being simple and easily comprehensible by those who are not deeply versed in the science.

* The *resistance* of a circuit is the opposition that it offers to the passage of a current. It increases directly with the length of wire, and inversely with its size, so that the longer the wire, and the smaller it is, the greater is the resistance which it offers to the current. Every bell offers a certain resistance. I have endeavoured to avoid the employment of technical terms as much as possible, chiefly because in the present condition of the science they are in a hopeless state of confusion. The few that I have introduced are intended to the comprehension of the subject.

detected by an increasing faintness in the ringing of the bell, and by a continued feebleness in the movements of the needles or indices that it actuates. When this is observed the battery should at once be examined and cleaned.

If a battery were constructed of pure and perfect materials its action would result in the continued formation of sulphate of zinc in the zinc cell, and in the continued consumption of sulphate of copper in the copper cell. It would, therefore, be only necessary occasionally to withdraw from the zinc cell, a portion of the sulphate of zinc, replacing it with water and to refresh the copper cell with crystals of sulphate of copper. But as materials cannot be obtained pure, several irregularities enter into the working of a battery, which interfere with its action and require investigation.

The water with which the cells of the battery are charged, if it be fixed in a dry place, evaporates, and leaves the battery dry. It must, therefore, be maintained properly supplied with water. It should never be surcharged with water. If the water reaches within an inch of the top of the battery it will be quite sufficient. A thin layer of oil upon the surface of each cell tends considerably to prevent this evaporation. It is for this reason also found preferable to place batteries in slightly moist positions.

When a battery has been for some time in action the zinc is found covered, and the zinc cell filled to a great extent with a "mud"-like substance. This mud is principally composed of pure copper, deposited upon the zinc by chemical affinity from the solution of sulphate of copper, which has permeated through the porous cell. It must be carefully removed, and retained in some receptacle appointed for the purpose, as it is commercially valuable, and tends to defray the cost of working the battery.

The porous cells are also frequently constructed of bad material they contain particles of coke or metal dust. Copper is then deposited upon them in patches. If these patches touch the zinc considerable local action sets in, wasting both zinc and sulphate of copper. When porous cells become encrusted with copper, they should at once be removed.

There is frequently a peculiar passage of liquid from the zinc to the copper cell through the porous partition, owing to a peculiar physical action called *osmose*, which raises the liquid in the copper cell an inch or more above the level of that in the zinc cell. It is assisted by the current. Its cause is not known. It usually occurs only when the battery is first set in action, and is easily corrected by the addition of a few drops of acid.

When the solution in the copper cell becomes exhausted of sulphate of copper, the sulphate of zinc, which has been formed in the zinc cell, passes through the porous partition, and deposits zinc upon the copper plate. This blackens the plate and reduces the action of the battery. Crystals of copper should, therefore, always be retained in the copper cell. They should be bruised into small lumps before being inserted in the cell, which should never be more than half filled with them.

When water contains lime (as almost all water does) part of the sulphate of copper dissolved in it is decomposed, forming a cloudy or jelly-like scum. This should be removed. It is, however, prevented from forming by adding a drop or two of acid to the water before the solution is made.

The water in the zinc cell, after continual use, becomes saturated with sulphate of zinc; this salt crystallizes upon the zinc plate, porous partition, and sides of the cell, and eventually impedes or stops the action of the battery. A portion of the solution should be occasionally withdrawn and replaced with water, and the crystals removed with a damp cloth. The formation of crystals on the porous cells is frequently checked by filling the pores of all the exposed parts with tallow, wax, or pitch, but cleanliness is the only real effective method of preventing any interference from crystallization.

After the continued action of twelve or eighteen months some of the zinc plates will be found so corroded and reduced in size as to become useless. They must be replaced with new plates.

A battery when it is first charged rarely assumes its full power until it has been at work for two or three days, but it can immediately be set in full action by the addition of a few drops of acid. This, however, interferes with its permanence, and should be avoided.

When a battery is cleaned the plates should be removed, and the divisions thoroughly rinsed and washed out; the plates well scraped and scrubbed, defective porous cells and zinc plates removed, and the battery again carefully charged.

It is an excellent plan in recharging the battery to make use

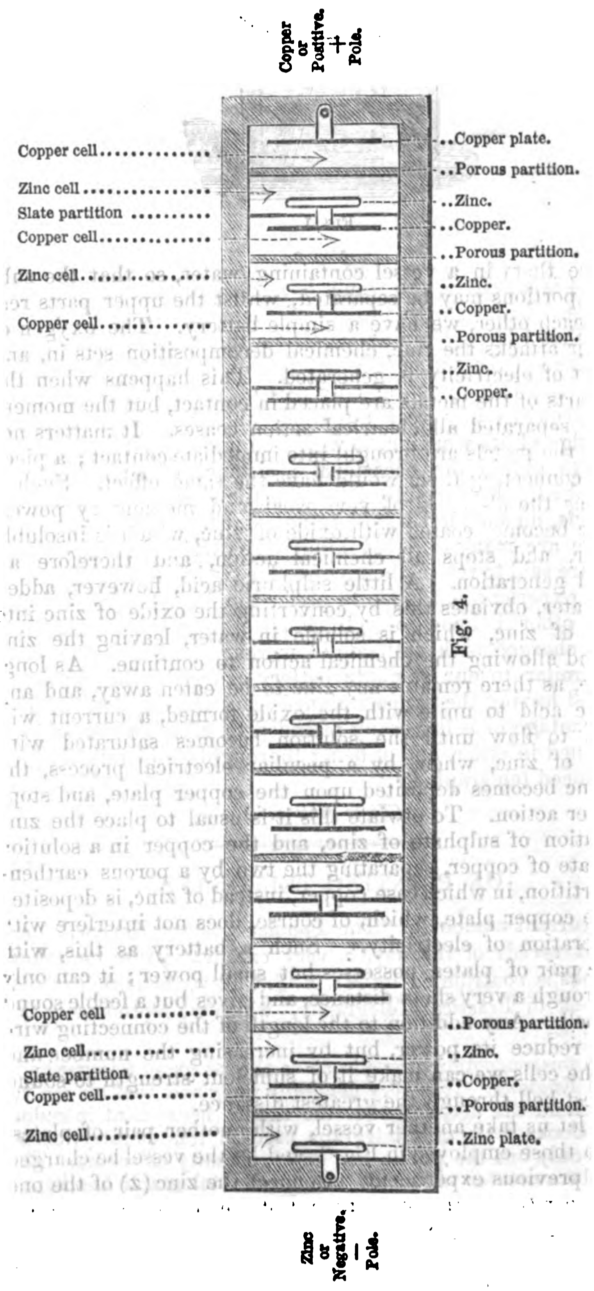

Fig. 4.

of the liquid which has been withdrawn from the zinc cells after the old plates have been removed preparatory to cleansing.

This can be done by a syphon or syringe. The liquid which has been withdrawn should be placed in a vessel containing a few pieces of zinc to reduce any copper that may remain in solution, and be reserved until the battery has been cleansed, the plates replaced, and the sulphate of copper deposited in the cells. The solution may then be distributed equally throughout the zinc cells, supplying each cell as far as the liquid will allow, and then filling up to within an inch of the top with water.

A defective cell, arising from a leakage or a broken porous partition, is sometimes found, reducing the power of the whole battery. In such a case it is a good plan to bridge it over thus—thoroughly clean the strap of the two battery plates between which the defect lies, and connect them across by a piece of wire, as illustrated in the following sketch :—

Copper. Fault. Zinc.

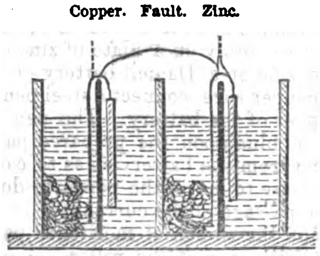

Fig. 3.

Fig. 4 is a plan of the whole battery, and Fig. 3 a section of two cells. I hope, with the aid of these two sketches, and the details that I have given above, that a thorough conception will be obtained of the action of a battery. I have been thus minute because the battery is the only part of the domestic telegraph which requires any real attention, and without a thorough knowledge of its working, it would be necessary for the householder to obtain the occasional assistance of an experienced telegraphist. By carefully following the above description and directions, no such aid would be necessary.

There are many different kinds of batteries in use, some of which are said to retain their power for twelve months or more; but my experience leads me to prefer the form I have described to any other I know of. In France they use an excellent battery charged with sulphate of mercury, and also one somewhat similar to our sulphate battery charged with sulphate of lead, and having the coppers tinned; but the one described has the advantage of being easily attended to, of being economically maintained in order, and of being thoroughly understood by our experienced telegraphists.

(To be continued.)

ON PRINTING TELEGRAPHS.

In the current number of "The Popular Science Review," one of the best serials of the day, a very excellent paper on printing telegraphs is contributed by Mr. R. S. Culley, the author of "The Handbook of Practical Telegraphy," which we reproduce in these columns :—

Much misconception prevails as to the progress telegraphy has made in England. It is very generally imagined that we are very much behind the age, and that the needle instrument introduced by Mr. Cooke is the only telegraph used in this country, because it is the only one the public has an opportunity of seeing. There cannot be a greater mistake. The needle telegraph has kept its place at our railway stations, and will keep it, perhaps, for many years, because of its simplicity, freedom from derangement, and the ease with which it can be repaired when out of order; but it is not used on any one important "commercial" circuit, even of the company which purchased the patent right.

The signals of the needle instrument, as is well known, are transient, and must be read off one by one as they appear, without a moment's hesitation. Though at the completion of each word the reader has the opportunity of saying that it is not understood, and obtaining a repetition, it may easily be imagined that if he give many "not understands," as they are called, the sender, who considers, naturally enough, nothing but stupidity prevents his signals being read, loses patience, and either reports the receiver as incompetent, or quarrels with him. Hence a tendency to guessing. These electrical quarrels are, in fact, one of the greatest sources of delay to messages, and damage to the apparatus, upon which the combatants vent their wrath as they cannot reach one another. Again, when an error arises, as it cannot be proved which clerk is to blame, it being impossible to determine whether the word has been wrongly signalled or read off inaccurately, neither the sender nor the receiver considers himself responsible. The feeling of responsibility is, however, amply secured by the printing system, for the signals are permanently recorded on the paper ribbon, or "slip," as it is technically called, and it is only necessary to refer to it to decide where the blame lies. The tendency to quarrel and talk is kept under control, for the slip, containing the whole conversation or quarrel, can be brought forward as evidence if required. And as the printed signals, if not perfectly legible at the first glance, can be studied, fewer errors occur in reading off. A far greater amount of accuracy is therefore attained by the recording apparatus than by any system of transient signals.

The simplest printing telegraph is that of Professor Morse, of America. The alphabet consists of dots and dashes, and though purely conventional, is easily learned. It has been altered from time to time, in order that accidental irregularities in the distance between the dots and dashes shall not transform one important word into another; and although England at one time possessed an alphabet better suited to our own language, it was found necessary, on the establishment of direct communication with continental cities, to fall in with the system in use abroad, and the same characters are now adopted throughout the whole of the old world.

THE MORSE ALPHABET.

The Morse apparatus has been adopted almost universally. It is sufficiently simple to be worked by any lad of ordinary capacity, does not really get out of order, and if deranged, can be set right with perfect ease. The dots and dashes, or "marks," as they are called, are embossed by a steel tracer or pencil upon a ribbon of paper, drawn forward at a uniform speed by clock-work; or written in colour upon the paper, by its being raised into contact with a small thin disk, covered with a peculiar ink. The latter arrangement produces more legible characters and requires less mechanical force than the embossing process, but needs a little more care.

The arrangement by which the electric current causes the pencil to touch and recede from the paper, so as to mark it, is this:— In the upper roller of the pair by which the paper ribbon is carried forward is a groove; under the rollers is a lever, pivoted at its centre, carrying at one end the pencil or style, and at the other end a piece of iron, which forms the *armature* of an *electro-magnet*, or horseshoe-shaped bar of iron, covered with insulated wire. This armature lies close to the electro-magnet, but does not touch it, being held back by a spring.

When a current is caused to pass through the wire, the horseshoe becomes a magnet, attracts the armature overcoming the resistance of the spring, and presses the pencil upon the paper; but as soon as the current ceases the iron loses its magnetism, and the pencil is withdrawn by the spring.

The duration of the current and length of the mark depend upon the sending-*key*. This key, in its simplest form, is merely a lever attached to the line-wire, or wire fixed from one station to the other, which, when at rest, connects the wire with the earth, but when pressed places a battery between it and the earth, so as to send a current to the distant station.

The clerk taps out his message by means of his key, producing a succession of currents which act on the electro-magnet at the distant station, attracting its armature, and embossing or printing corre-

sponding dashes and dots upon the paper band as it passes forward between the rollers, recording every movement of the sending-key.

On the conclusion of the message, if it is legible, the number of words is counted; and if correct, the receiver acknowledges it by sending back certain signals serving to identify it, followed by · — · — RT "right" (in America, O K, "all correct"). This acknowledgment appears on the slip of the sending station; and in case the message should not reach the person for whom it was intended, can be produced as a proof that it was duly transmitted.

The paper ribbon is cut in long lengths, and each roll is kept entire and unbroken, so that every signal may be registered in its proper place. If this were not done, the record would be useless as a check, for dishonest clerks would be tempted to manufacture acknowledgments, and to destroy messages which they had neglected to deliver. The unbroken record prevents any such alterations and erasures.

Much has been said of the superiority of the American telegraphists, because they are able to read the Morse signals by the sound made by the electro-magnet; and of the great saving in expense effected by dispensing with the paper slip. By this plan the advantage of the record is at once lost, and the Morse apparatus used as an acoustic instrument is not, in our opinion, either as rapid or as accurate as the bell telegraph of the Messrs. Bright. It is not from a want of ability to read by sound that the system does not prevail here, for the English staff converse among themselves by almost inaudible taps upon the table, which has the merit of being a much more correct and rapid method than that adopted by the spiritual intelligences who favour us with their conversation, but who do not seem to have made much progress in this particular department of knowledge. Our clerks also talk by a slight movement of the forefinger or thumb, imperceptible to the uninitiated, which would be a wonderful assistance to clairvoyants and conjurors. Indeed, Robert Houdin employed some such means in his celebrated "second sight" experiments.

The Americans, however, because of a peculiarity in their system, can beat us in one particular. When in the open country, they can read what is passing on a wire by cutting it and putting its two ends into the mouth, and can reply by tapping them together, without any apparatus whatsoever.

In the earlier days of telegraphy, it was impossible to obtain legible signals at distances over 200 miles, even in dry weather, and during fog or rain it was necessary to transmit messages by reading them off at an intermediate station, and forwarding them on afresh; so that a message from London to Glasgow would be repeated twice, or even four times. Owing to the great improvements in insulation, distances of 400 miles now offer no obstacle to direct communication in all weathers.

The Morse instrument has the great advantage of being capable of acting as an *automaton clerk*, and transmitting its own signals. The movement of the lever which carries the armature and style is limited by two screws, between which it oscillates with considerable force. It can, therefore, be easily made to perform the function of a key, so as to forward the message a second stage, where the same process may be again repeated.

By means of a series of such relays, direct communication is effected between London, Berlin, and St. Petersburg, or even more distant cities.

We have described the Morse apparatus in its simplest form, for the limits of our paper do not permit enlarging upon the contrivances for neutralising the effects of induction in submarine cables, for cutting off the leakage from neighbouring wires, and for increasing the sensibility of the apparatus. It is, however, necessary to mention one point. As it is not possible to transmit to a great distance a current sufficiently strong to produce a powerful mechanical action, the current received from the sending station is made to act on a relay connected with as powerful a battery as may be required to set in motion the Morse apparatus.

The speed attained by the Morse system varies with the nature of the despatch. Intelligence or news can be worked off much faster than private messages. A first-rate clerk has been known to send between sixty and seventy Stock Exchange messages per hour, but thirty to thirty-four words per minute is excellent work, the receiver, of course, writing for himself.

Owing to the facility afforded by the system of transmission by relay, or as it is called, *translation*, despatches can be sent to stations, on separate and distinct wires, at the same time by a single clerk. The debates in Parliament, Reuter's telegrams, and the other items of telegraphic news which appear in the country papers, are now frequently manifolded in this manner—to six, seven, or even more stations at the same time, and it would be quite possible, if it were desirable to do it, that a single clerk in London should supply every large town in the kingdom, at one and the same moment.

The printing telegraph first used here, and still partially employed, is, however, not that of Professor Morse, but an invention of Bain, of Edinburgh, founded on the chemical effects of electricity. When a current is caused to pass through the solution of a chemical compound, it decomposes it, or separates its component parts, in many cases producing an alteration in colour, either by causing the wire which conveys the current to be dissolved, or by separating a coloured solid substance from a solution previously colourless. Thus if a current be made to pass through paper soaked in iodide of potassium, iodine, a solid substance, will be separated at the wire connected to the copper of the battery, and a brown stain will be produced. Soak a sheet of printing-paper in a mixture of equal parts of saturated solutions of the ferrocyanide of potassium and nitrate of ammonia, diluted with an equal volume of water; blot it off and lay it smoothly on a plate of zinc or sheet of tinfoil, connected with the zinc of a Daniell battery of twenty cells. By means of a flexible copper wire, connect a steel pen fixed in a wooden holder with the copper of the battery. The pen will now be found capable of writing in blue upon the prepared paper; but if either wire be disconnected from the battery so as to cause the current to cease, the pen will cease to mark, the power to do so being entirely dependent upon the passage of the current.

In Bain's telegraph the ribbon of moistened paper is carried forward by clockwork over a metallic roller. A pencil of iron wire rests upon the paper, and is so connected that the positive current flows from the iron to the paper, producing signs similar to those of Morse.

The apparatus we have described is so simple and so easy to manage, that it will always be extensively used; nor is the peculiar alphabet as great a disadvantage as it may seem, for there is no real difficulty in acquiring a knowledge of it.

The instruments which print in ordinary letters by the pressure of inked type are extremely complex, and though, from the fact that each letter is formed by the simple pressure of a key like that of a pianoforte, it might seem they are easily worked, the fact is, so much skill is required to manage them and to print at a sufficiently high speed, that they are at present practically unremunerative. The most important instrument of this class is that of Professor Hughes, of New York. The apparatus at all the stations is precisely alike, and consists of a keyboard like that of a pianoforte, containing as many keys as there are letters, figures, and marks of punctuation to be printed. Connected with the keys is a set of moveable pins arranged vertically in a circular frame, through the centre of which passes an upright shaft, kept constantly revolving by clockwork. Hinged upon this shaft is an horizontal arm, which sweeps round continually a little above the circle of pins. If one of these pins be raised by pressing the key with which it is connected, the arm will touch it and slide over it in passing, establishing contact with a battery. A wheel on the edge of which the letters are engraved, is driven by the clockwork which keeps the horizontal arm in motion, and is so arranged that whenever the arm passes over the pin corresponding to a given letter on the keyboard, the letter itself on the type-wheel is opposite the paper. If the speed of the distant instrument can be so regulated that its type-wheel shall move in perfect accord with that of the sending station, and if the paper ribbon at both stations be pressed upon the type at the same instant, the same letter will be printed at each. The pressure necessary for printing is produced by the current sent by the contact of the horizontal arm with the raised pin, which acts upon an electro-magnet and removes a catch or detent, permitting the wheelwork to raise the paper so as to touch the type. In order to obtain sufficient speed, it is necessary that the type-wheel should revolve at least 120 times per minute; and it will easily be understood that there is great difficulty in so regulating the receiving machine that at this high velocity it shall neither lose nor gain upon the sender. The adjustment is obtained by means of a vibrating spring which acts as a pendulum, and small differences in speed are adjusted before the printing of every letter by the machine itself.

M. Dujardin is engaged in perfecting a type machine on a different principle. Want of space compels us to omit the description of this and other methods of type-printing equally ingenious.

(To be continued.)

THE INTERNATIONAL EXHIBITION, 1862.

(Continued from page 174.)

(*d.*) *Step-by-step Type-printing Instruments.*—The only new type-printing instruments, besides that of M. Bonelli, are French step-by-step instruments, which may be conveniently described here.

Messrs. Digney, Paris (France, 1,414), exhibit a modification of the dial instrument, which converts it into a very simple type-printing instrument. They work the escapement moving the type wheel with, say, a positive current and interruptions, by means of a steel magnetized armature in front of the two poles of a double electro-magnet, which repels the armature when a positive current passes, but attracts it when no current is passing, or when a negative current arrives. At the back of the electro-magnet is another magnetized steel armature which, on the contrary, is only repelled when negative currents arrive; it is used to close the local circuit which prints the letters, and moves on the paper in the usual manner. In their transmitter, so long as the handle is turned round, positive currents only are sent, separated by short interruptions, as in M. Bréguet's step-by-step instrument; both a current and an interruption are required for each letter. These currents move the type wheel round. When the handle has arrived opposite the letter required, it is pressed down for a moment, making a contact which sends a negative current into the line, and this current, by moving the second armature, prints the letter. This instrument prints about nine words per minute.

P. A. J. Dujardin, Lille, M. (France, 1,439), exhibits a step-by-step type-printing telegraph of remarkable merit. The transmitting instrument has the disc and sinuous groove, common to all the French instruments of this class. It sends reverse currents by a very simple key moved from this groove, and is so arranged, that when the handle is depressed the current is broken. The reverse currents work a step-by-step propelment, which brings the required letter opposite the paper, and the printing is effected by the interruption of the current. The type wheel is quite novel, and it is probably to its peculiar construction that M. Dujardin owes the success of his instrument. It consists of a small flat disc made of very thin aluminium. The letters are, as it were, sewn in a circle round the face of the disc (not on its edge), a hole corresponds to each corner of the letter, and silk passing in and out defines its form. The depression of an inked pad over any one of these letters presses it on the paper, where interruption of all currents is also worthy of notice. There the silk leaves its mark, and at the same time receives a fresh charge of ink from the pad. It is difficult to imagine that any lighter and stronger type wheel could be constructed. The plan of determining the impression by the electro-magnetic coils, through all of which the received currents pass, move three cylinders of soft-iron to the left or right with positive or negative currents respectively. One of these cylinders works the escapement of the letter disc by its oscillations. The two others are so arranged that, when no current circulates through them, the right-hand cylinder is moved to the left, and the left-hand cylinder to the right, by springs. When they are both in this position they close the local circuit, which brings the pad down on the type wheel and prints a letter. The received currents pass through all the coils either in multiple arc or in series, as best suited to the circuit with which they are working.

So long as reversals are received, the three cylinders move parallel to one another, first all to the right, and then all to the left, moving the type wheel round, but leaving the pad unmoved; so soon, however, as the currents cease to pass, the type wheel and its cylinder stand still wherever they may be; the two other cylinders, instead of remaining parallel, come together, close the local circuit, and print the letter. As soon as currents begin to arrive they again take up their parallel position, breaking the local circuit, lifting the pad, and moving the paper on a step. It is worthy of remark, that by this plan the same letter can be continually repeated without moving round the sending arm by simply raising and depressing the handle. The cylinders spoken of perform the functions of the armatures in common electro-magnets. They are all similar, and consist of a long hollow cylinder of soft-iron centred on an axis perpendicular to the axis of the cylinders in the middle of their length. One half of the cylinders passes into the hollow centre of the receiving coil, and the end even passes a little beyond it. Positive and negative currents passing through the coil alternately magnetize this cylinder in one and the other direction. The two poles of a powerful horseshoe magnet are placed to the right and left of the end of the cylinder, which, as it is magnetized in one direction or the other, oscillates backwards and forwards between those poles.

This arrangement can be worked by weak currents. The instrument exhibited was worked successfully by thirty-two Daniell's cells in circuit, with Messrs. Digney's resistance coils, equivalent to 700 kilometres* of iron wire, 4 millimetres in diameter, printing about twenty words per minute; and two similar instruments worked regularly for three months between Paris and Lille, a distance of 280 kilometres, or 174 miles.

By a slight alteration in the connections the two coils, which determine the printing when their cylinders are parallel, can be made to act also as a relay to work the propelment coil, which is then, of course, not in the same circuit. They could also be used to translate reverse currents into a second line.

M. Dujardin received a medal for this instrument.

L. C. Guyot D'Arlincourt, Paris (France, 1,444), exhibits a step-by-step printing instrument of great complexity. The coercive force of soft-iron is used to determine the impression of the letters in a manner which has been frequently proposed. The momentary reversed currents which work the step-by-step propelment are of too short duration fully to magnetize a large electro-magnet, the armature of which by its motion determines the impression of a letter at each pause in the transmission, when a permanent current is transmitted.

J. W. Brett (United Kingdom, 2,853) exhibited the same printing instrument as was shown by him in 1851. It has not come into general use in this country.

In 1851 several step-by-step instruments were exhibited, the index of which returned to zero after each letter, so that a constant number of currents was required for each letter, which thus became independent of those preceding it. This apparent merit has evidently been found of little importance, for on the present occasion not one instrument of this kind is shown.

9. *Automatic Letter-printing Instrument without Step-by-step or Synchronous Motion.*

Chevalier G. Bonelli, Turin, M. (Italy, 1,227), exhibits an automatic system of transmission, which differs essentially from the four plans before described, inasmuch as the message is prepared for transmission in the ordinary Roman type, and is received or printed in the same letters. The plan resembles to some extent that of Bakewell, exhibited in 1851, but differs from it inasmuch as the synchronous motion of the instruments at the two ends of the line is dispensed with by the use of a large number of conducting wires instead of a single one. M. Bonelli, like Caselli, uses reverse currents to act on the electro-chemically-prepared paper.

M. Bonelli composes his messages in Roman type of the ordinary construction. He then passes the arranged type under a little comb with ten equally spaced teeth, which just cover the breadth of the type (which is about 0·17 inches wide). These ten teeth are all insulated from one another, and each is connected with its own line wire. Thus, ten distinct line wires are required. At the receiving station each wire is in connection with a corresponding tooth of a similar comb, which rests on the chemically-prepared paper. Each of the teeth of the sending comb as it comes in contact with the projecting portions of the type sends a current through its line wire, which is marked with the corresponding tooth by an electro-chemical reaction on the prepared paper, as it is drawn under the receiving comb at approximately the same speed as the type passes under the sending comb. In fact, each line wire with its sending and receiving tooth may be looked upon as a separate Bain's system, with one important difference, to be mentioned presently. Each line, therefore, transmits only points or strokes, but these points and strokes are so grouped as to correspond with the projecting portions of the type, so that the dots and lines from the ten wires will be distributed in groups very accurately representing the letters. With ten distinct wires or rows of dots and lines the letters are extremely well formed: M. Bonelli states that seven would be found practically sufficient.

The arrangements for sending and receiving the messages are very complete, and sufficiently simple. A sort of long car at each station is driven by a weight along rails, and its speed is regulated by a fly. Along one end of the car is placed the message in type to be sent; this message cannot greatly exceed twenty words. Along the other end of the car a piece of moist prepared paper is placed. The two cars at the two stations start at about the same

* This is equal to about [illegible] miles of No. 8 iron wire.

time; each sends and each receives a message of about twenty words during one traverse of the car. One station sends during the first half of the journey, and receives during the second half, while the other sends during the second half, and receives during the first. A fresh type-stick is then placed on each car with clean receiving paper; the cars are moved back to their original position by hand, and the operation is repeated.

M. Bonelli could not make use of Bain's chemical reaction, for this depends on the gradual consumption of an iron point, whereas it will readily be seen that M. Bonelli's little combs must remain unworn. He uses a solution of nitrate of manganese, which, under the action of a positive current, precipitates oxide of manganese. Without the discovery of this, or some similar method of marking, M. Bonelli's invention would have been impracticable.

The points of the combs are made of a platinum-iridium alloy. The sending comb can rock slightly on an axis, so as to press lightly on the type passing beneath. The receiving comb is fixed, as the moist paper beneath yields readily to the pressure. There is also a contrivance for sending reversals at each signal through each line: a positive current each time a tooth comes in contact with the type, and a negative current whenever it is insulated. This was rendered necessary by the polarization which otherwise occurred at the points of the receiving comb, where the accumulated products of the reaction from successive similar currents prevented the regular passage of the true received currents.

M. Bonelli, however, obtains these reversals at a great waste of battery power. The negative poles of the batteries at each end are permanently in connection with the lines, of which, for the moment, we will consider one only. He further arranges his connections so that the contact with the type connects the whole of the battery at the sending station with a short circuit, and at the same time supplies an earth connection to the battery at the receiving station. The positive pole of one part of this battery is connected with the earth through the receiving paper, and a positive current from that part of the battery consequently flows through the paper at the receiving station as soon as the other pole finds an earth connection at the sending station, or, in other words, whenever the type contact is made; when this contact is broken the home short circuit is also broken, and the negative current from the whole of this battery overpowers the current in the opposite direction from the smaller section at the receiving station, and so the negative current, partially neutralized, passes through that battery, and through the paper to the earth. Thus, one of M. Bonelli's currents is the result of a difference between two antagonistic batteries, and the other is only obtained from the smaller section of one battery at the expense of allowing the larger to send a current through a short circuit. The batteries, moreover, require to be powerful; each wire on a short circuit requires from fifteen to twenty cells at each end, and in practice M. Bonelli expects to use at least sixty cells per wire, or 1,200 cells with ten wires for two stations only.

The expense of first cost and maintenance would obviously be considerable. On the other hand, M. Bonelli expects to transmit 500 messages of twenty words every hour, using two cars at each of the two stations, one of each pair to receive and send while the other is being prepared. Each message of twenty words, allowing for a little lost time, would thus require to be transmitted in about five seconds, and this was done with ease before the jury, when a short circuit only was used. These twenty words represent about 100 letters, and as many as nine reverse currents are frequently sent on one wire in the course of each letter; thus, the above speed requires 180 reversals per second, or 10,800 reversals per minute, through each wire.

It is very doubtful whether this enormous speed can at present be realised over lines of any length, where induction and leakage come into play. Even Professor Wheatstone's automatic transmitter, sending 600 letters per minute, does not require more than about 4,000 reversals, and it is still doubtful whether this speed can be attained in practice on lines of any length, even with the most sensitive electro-magnetic receiver. Moreover, to effect the electro-chemical reaction, powerful and well-separated currents are required. The system is, however, shortly to be tested practically, and certainly exhibits many points of interest. Even if successful, M. Bonelli's claim must rest on the fact that his messages are printed in common legible characters, instead of in symbols; for the other automatic systems exhibited would considerably exceed him in speed. Thus, Messrs. Siemens with ten wires would transmit 800 words per minute, and Professor Wheatstone 1,200; whereas M. Bonelli can only promise 166, or, not allowing for stoppages, say 240.

10. *Special Application of the Electric Telegraph to Railway Signals.*

Few applications of the electric telegraph are more important than its use in connection with railway traffic. In many parts of Germany, and on some lines in England, no train is allowed to pass any station until the departure of the preceding train has been telegraphed from the station in advance. This plan was first proposed by Mr. Cooke, and is known as the "block system." When this system can be strictly adhered to, collisions are clearly impossible, but its general adoption would necessitate the establishment of several telegraphic stations between each passenger station, as it would otherwise restrict the traffic on most English lines within very inconvenient limits; whatever code of rules and signals be adopted, it is clear that the management of a line is greatly facilitated, and its capabilities for traffic greatly increased, by the electric telegraph.

The common needle instrument is much used for railway purposes, and from its simplicity has some advantages. A signal received by it may, however, escape attention, or may even be misunderstood, and the message leaves no record. This defect has been remedied by the use of a permanent current maintaining the needle deflected to one side when the line is clear, and to the other side when it is blocked. Electro-magnetic bells have been introduced by Mr. Walker, instead of the needle instrument, as the sound can hardly escape attention. Mr. Walker's or other electric bells are also now generally used in connection with the needle instruments to draw attention to the deflections. Mr. Tyer with one wire only, and momentary currents, works a system of bell signals combined with a permanent visible record of the last signal sent and received.

The Universal Private Telegraph Company [Professor Wheatstone, Juror] (United Kingdom, 2,978) exhibit a simple form of Professor Wheatstone's step-by-step magneto-electric dial instrument, adapted for railway signals. The twenty-six letters of the alphabet are in this instrument replaced by six signals on the dial, but the number of teeth on the propelment, and the number of currents sent during one revolution of the sending arm, remain as before; by this arrangement the loss of one or two steps is rendered of no consequence, since the index will even then be brought so near the signal required, as to show clearly which is meant. The continuous motion of the armature in front of the coils is therefore unnecessary, and the armature of this instrument is stopped and started by hand in the old manner. An alarum is sounded at each signal, and the signal received and sent remains permanently visible. It is obvious that, instead of six different signals, a larger or smaller number could be used at will.

C. V. Walker, H. M. (United Kingdom, 2,983), exhibits the bell railway signals first introduced by him on the South-Eastern Railway in December, 1851. There are now 321 of these instruments at work. The hammer of the bell is attached to the armature of an electro-magnet, the coils of which are of very large dimensions, and formed of thick wire. The signals are sent by a common contact key, and one blow is struck on the bell for every contact made. An arbitrary code is used in which the signals depend on the number of blows.

Mr. Walker occasionally so arranges the bells that a guard of a train delayed between two stations can signal to the stations on either side of him without any battery. This is effected by maintaining equal but opposite (and therefore balanced) currents constantly on the line from the two stations; when either station connects the line with the earth the other station receives a signal, and when the line wire is connected with the earth at any intermediate point both stations receive a signal. The means of making this temporary connection are provided at certain telegraph posts at short distances. One of the instruments exhibited has an index attached, worked by a simple propelment, to show on a dial the number of currents received. The bells are worked direct, or without a relay, over distances of about ten miles, with thirty of Mr. Walker's graphite plates.

Together with these bells, Mr. Walker shows two contrivances for registering the signals sent and received: one, called the globotype, registers by different coloured balls dropped into a long inclined channel from different tubes by valves or traps worked by different electro-magnets. One colour denotes signals sent, a second signals received, and balls of a third colour are dropped at fixed intervals determined by a clock. Thus, the succession of the signals,

and the time at which they were sent or received, can be verified at any time during the day. The same object is effected by the linoscribe, the second contrivance alluded to, which depresses a thread of cotton into one or another coloured ink, when one or another armature of various electro-magnets is moved; the thread is at the same time pulled forward a little way. These two latter instruments have been used, but Mr. Walker does not recommend their adoption owing to their complexity.

(To be continued.)

MODERN WONDERS IN TYPO-TELEGRAPHY.

It will not be necessary in this journal to say much about the general principles of electro-telegraphy; most of our readers know that the moving power is sometimes galvanism, sometimes magneto-electricity; that sometimes one wire, sometimes several, transmit the impulse; that this impulse travels an immense distance in an almost inappreciably short space of time; and that the wires may pass through air, earth, or water, provided proper insulating means be adopted. But one matter which is not so well understood is this—What kinds of signals are used; or, more exactly, how are the messages put into form at one end of the line, and recorded at the other?

Up to the present time arbitrary signals are employed more extensively than alphabetical letters to express the message. Some systems do not use any alphabet at all, properly so called; for the operator, by moving a handle to and fro in various directions, makes a needle simply *point* to the letters of the alphabet as they are wanted; and the impulse transmitted along the wire causes the needle of the receiving apparatus to point to similar letters. Most inventors are, however, now directing their attention to such forms of apparatus as will enable the telegraph actually to *write* or *print* its message on paper, either in the ordinary alphabet, or in some arbitrary characters. Professor Morse's system consists of a series of dashes and dots, the lengths, positions, and distances of which are made to denote different letters or signals. No matter whether the letter A is represented by a dash, or a dash and a dot; if the particular symbol is agreed upon, either will suffice. The recording instrument at one end marks on paper a series of dashes and dots; the receiving instrument at the other end marks almost simultaneously a similar series of dashes and dots; and a printed code for the service of the clerks enables the receivers to read the meaning of the senders. Professor Steinkeil's system dispenses with dashes, and forms all the symbols for letters by variously distributed dots, marked on chemically-prepared bands of paper. In both of these systems care is taken that the letters most frequently used shall be expressed by the shortest groups of symbols. Mr. Whitehouse, Mr. Allan, and Professor William Thomson have all devised ingenious forms of this dot system, applicable to various developments of the telegraphic apparatus. In order to produce the dashes and dots here adverted to, various hand-worked contrivances are employed. Morse's dash-and-dot signals are usually transmitted by a simple rocking lever, worked up and down by hand between two stops. The British and Irish Magnetic Telegraph Company, and some other telegraphers, employ an apparatus in which the finger presses down a key, connected with a lever by which the dash-and-dot writing is effected when the electric current is in proper action. Numerous other little contrivances are adopted by various inventors and companies, in which the hand or finger is employed to make successive movements on levers or keys, to produce the various systems of dashes and dots through the medium of the electric current. Then, at the other end of the copper wires—say a hundred miles away—is a receiving apparatus, to which the dashes and dots tell some sort of tale or other, comprehensible to the receiving clerk. The modes of doing this are very diverse. The *needle* instrument, hitherto much employed, comprises certain small magnets which, put in action by the electric current, move an index needle; and the receiving clerk, observing these movements, determines from them the number and order of the dashes and dots, and interprets the message accordingly.

In Professor Morse's recording instrument a small magnetic apparatus, influenced by an electric current received from the other end of the wire, causes a metallic point to press momentarily on a strip of paper; the paper is drawn forward at uniform speed by clockwork, and the momentary and often-repeated pressures by the metallic points leave on the paper a series of slightly-embossed marks of various lengths, which the receiving clerk can read by means of his code of signals. In Messrs. Digney's apparatus, the embossed marks are superseded by ink marks, which are more legible and more permanent. A small circular disc is kept moistened on its edge with ink from a saturated felt roller; the disc is made to revolve, and the travelling strip of paper is made to touch it for minute portions of time; and thus the message is delivered at the receiving end in the form of inked dashes and dots. The embossed lines and dots are much used in the telegraphic systems of Germany and Switzerland; the ink lines and dots are coming largely into favour in France. Many new modes have been recently introduced for applying the ink to the edge of the disc. At the present time, a problem remains to be solved by the electro-telegraph companies, whether to adopt an *acoustic* or a *recording* receptive apparatus; the electric wire can ring a bell as well as mark permanent dashes and dots; signals conveyed by the former means are not permanent, but are cheap to manage, while those by the latter means are more expensive, but are permanent; it is probable that the exigencies of commerce will find suitable employment for both systems.

Wholly distinct from the above are the *dial*, or, as some call them, the *step-by-step* telegraphs. They are all modifications of the first dial telegraph introduced by Professor Wheatstone in 1840. The pervading principle of them all is, that letters are marked circularly on a dial, and that the operator spells out the letters of his message by moving round a handle until an index points to the particular letter wanted. The electric wire, put into activity by this means, causes a similar index to point to a similar letter on a similar dial at the receiving station, or records the signals by any one of several other means. Instead of a lever, most of the dials have finger-stops, each one to be touched according to the letter near which it is placed. The disadvantages of most of these dial telegraphs are said to be, that the correct transmission of each letter depends on the correct reception of the foregoing letter; insomuch that one error in the reception throws all the subsequent letters wrong; and that the number of currents required for each signal is so large as greatly to increase the chance of failure. On the other hand, any person who can read or write can send and receive signals by these means; and, as no battery is wanted, the instrument is always ready.

We have now an important advance to notice. In the various systems hitherto described, the signals, whatever they may be, are produced by hand, each requiring a separate act of volition and a separate movement of the hand. But there have been devised modes of so employing *automatic* mechanism as greatly to increase the rapidity of transmission—or rather, to increase the number of messages that a single wire could convey within a given time. In all these new methods, the message is in some way mechanically represented, say by punched paper or by arranged type. Several clerks may be engaged in another room, without any necessary knowledge of electric telegraphy, in punching the paper or arranging the type; and then, when the messages are once prepared, they can be transmitted with wonderful rapidity along the wire. Professor Wheatstone's Universal Private Telegraph acts upon this plan. A strip of paper is made to pass slowly along a groove; the finger, pressing on certain keys, causes three punches to punch holes in the paper; and those holes, by their sizes and grouping, are made to represent letters and words. When a strip thus prepared is drawn through the electric machine, it causes an apparatus at the other end of the line to write down the message in similar characters. The time consumed is in *preparing* the message; the *transmission* is almost instantaneous. The most expert clerk cannot signal more than about 120 letters per minute by the hand method, whereas 600 can be transmitted when the letters are punched beforehand. Mr. Allan has a similar mode of using punched paper; but the depression of a single key punches all the group of dot-holes for one letter. Messrs. Digney punch the strips of paper with long or short rectangular holes, to produce their code of dashes and dots. Messrs. Siemens & Halske, instead of punched paper, use moveable types of metal, each type presenting an alternation of ridges and hollows not like the ordinary letters of the alphabet, but such as will produce dashes and dots.

In connection with Wheatstone's *automatic* (as distinguished from the *voluntary*) system, a suggestion has been thrown out of so remarkable a kind, that we are induced to give it in the words of the original. It occurs in the Report of the Jury on Electrical Instruments at the International Exhibition in 1862:—"If the public could be induced to learn a telegraphic alphabet, and to *prepare their own messages*, the success of the automatic system

might be expected with much confidence. Thus a merchant's clerk might prepare the messages of the firm in the punched paper required for Professor Wheatstone's transmitter. This prepared paper, on delivery at the telegraph office, would simply have to be passed through the machine when its turn arrived; and the corresponding dotted tape at the distant station could at once be addressed and delivered, to be deciphered by the receiver at his leisure. The functions of a telegraph company would then be nearly similar to those of the present post-office. The messages of prepared paper received would have to be sorted and transmitted in batches to the several towns by being passed through a machine at one end of a wire, at the other end of which the counterpart would appear. These counterparts would then have to be again sorted, addressed, and sent out as letters are now. Every yard of paper sent through the machine might be charged at a certain rate, without any reference to the code, language, or number of words. No great skill would be required to prepare or decipher the message, since these operations could be done leisurely; the functions of the company would be reduced to those strictly essential, and their responsibilities much diminished. Although seeming somewhat visionary at present, it is just possible that some such plan may some day be adopted, and that telegraphic dispatches may then be sent as cheaply as letters are now."

There is now being brought under public notice a system invented by M. Bonelli of Turin, the contriver of the very singular and beautiful electric loom for weaving; it is an improvement on an apparatus displayed by him at the International Exhibition in 1862. Unlike the other systems hitherto noticed in this article, Bonelli's telegraph *prints the message in Roman type*, such as is familiar with every school-boy. There are no arbitrary dashes and dots here. The types are Roman capitals, about one-eighth of an inch high—or rather, they are midway in character between Roman and Egyptian capitals. They are cast in ordinary type-metal, and can be arranged in a long line of words after very little practice. Suppose a Manchester manufacturer wishes to ask a Liverpool shipowner, "At what hour this evening will your vessel sail for New York?" The types to form these words are "set up," as a compositor would term it, from a fount or large collection ready at hand, proper blank spaces being inserted between the words. They are arranged all in a row, and are fixed upon the face of a narrow sliding bar. The bar is carried to a small electric apparatus, through which it is passed slowly. The surface of every type, as it passes, is touched by a comb of five metal teeth, connected with five copper wires. Each tooth, when it comes in contact with the projecting portions of the type, sends a current through its line of wire; whereas no current passes when the tooth passes over the hollow portions of the type. At the other end of the line (say at Liverpool) is an apparatus with a row of five metal points. A strip of paper, steeped in some chemical solution, is made to pass under these points; and according as electric currents are or are not passing through any or all of the wires at any given instant, so do the five points make five lines of little interrupted dashes on the paper, so ingeniously contrived as to length and mutual distance as to produce very good imitations of Roman or Egyptian capital letters, similar, in fact, to the type employed at the other end. The metal points decompose the chemical solution with which the strip of paper is wetted, and produce a kind of brown stain sufficiently legible for all practical purposes, and also durable or permanent. The row of five points is producing this writing or printing on prepared paper almost at the very identical instant when the comb of five teeth at the remote telegraphic station is passing over the surface of metal types. Were it not that we have almost ceased to wonder at anything which electricity can achieve, we might well marvel that, in this system of typo-telegraphy, the *type* are at one end of the line, and the *printing* at the other. A printer, fed with electricity, instead of with beef and mutton, prints on a slip of paper which is or may be hundreds of miles distant; for the system has been successfully tried, not only between Liverpool and Manchester, but between Paris and Boulogne. A sort of long low carriage, travelling along a miniature railway on a table, receives two sliding bars in two grooves, and passes under and in contact with two combs of five metal points each; one sliding bar contains a line or row of arranged type; the other has laid upon it a strip of moistened prepared paper; and if two operators at two distant stations have properly signalled each other, one motion of the carriage will transmit a message in one direction, and *receive* a different message in the opposite direction. Nothing is more curious than to see this double process going on under our eyes. The assertions made by joint-stock companies are often of the *couleur-de-rose* kind, and therefore we cannot positively affirm that "the average time occupied in setting into type a message of thirty words is a minute and three quarters;" that "the time of transmitting such a message is six seconds;" that "five compositors at either station can compose from three to four hundred messages per hour;" and that "eight such compositors, in less than an hour and a half, could have set up the whole of Mr. Bright's celebrated Rochdale speech, consisting of forty-nine thousand letters." But though we cannot vouch for this, we can answer for the beautiful and ingenious way in which scientific principles are here combined to produce a certain desired result.—*Chambers's Journal.*

MR COOKE'S PAMPHLET OR SKETCH OF 1836.

The early history of the Electric Telegraph has hitherto been but imperfectly told. Numerous works have been published from time to time; the authors, however, appear to have had but a limited acquaintance with the toils and anxieties of those to whom we are indebted for the adaptation of electricity to a practical system of telegraphing. There were not the facilities at that time which we now possess to make known the progress of discovery. The scientific works were expensive and few in number, and the daily press, with one or two honourable exceptions, rendered no assistance in preparing the public mind to receive the electric telegraph as a project capable of practical application. The inventors, Messrs. Cooke and Wheatstone, however, toiled incessantly, overcoming all difficulties, until at last the "wonders of the wire" could no longer be ignored. We publish this week the first portion of a pamphlet written by Mr. William Fothergill Cooke in the year 1836, in which he pointed out the advantages to be derived from the application of electricity for telegraphic purposes. Our readers will be able to judge how far the suggestions which it contains are carried out. It contains many valuable hints which might be beneficially adopted, even at the present advanced state of the telegraphic science.

We have often heard the question asked, how is it that two gentlemen, who have by their joint labours conferred on the civilized world such vast advantages, are allowed to remain without some special mark of approbation?

Plans for establishing on the most extensive scale, and at trifling expense, a rapid telegraphic communication for political, commercial, and private purposes, especially in connection with the extended lines of railroads now in progress, between the principal cities of the Kingdom, through the means of electro-magnetism, by William Fothergill Cooke.

The Inventor of the instrument and system which are the subjects of the following pages has availed himself of an idea suggested many years ago by a Mr. ——, of ——, and since renewed by Professor Weber, of Göttingen, under a varied form. Mr. —— proposed to convey along isolated wires, a series of electric shocks, which, according to their number, would have reference to a signal key of letters or sentences, &c. Professor Weber, in 1832, struck by the amazing rapidity with which a suspended magnetic needle obeyed the impulse of a galvanic current conveyed along a great length of wire, proposed employing it for telegraphic purposes, the easterly and westerly deviations caused by reversing the direction of the current offering an alternation of two symbols. The apparatus hereafter mentioned is worked on a different principle altogether, the galvanic agency being, however, still employed.

The national importance of some practicable method by which the benefits of a rapid telegraphic communication may be extended, at a cheap rate, to political and mercantile affairs, and, in all cases of emergency, to the private concerns of individuals, is too obvious, either to require argument, or admit of question; and it seems only to be needful that a clear statement should be given of the manner in which this object may be attained, to ensure general encouragement and support for the execution.

Improvement, however, which in every other department involving the convenience and exigencies of society, has, especially of late years, made the most rapid and unexampled progress, we find inactive here.

The enormous expense attending the present system of telegraphing, whilst is offers an insuperable obstacle to the establishment of a line of telegraphs for any objects but such as are of the most essential importance, is felt even by Government as a sensible weight in the short line between London and Portsmouth, the solitary instance in which it has been called into action, even in affairs of state.

This expensive system labours also under the following very serious deficiencies and imperfections, which, necessarily arising from the principles on which it is framed, admit of no remedy:—

I. The present telegraph is only available during day-light, *i.e.*, during less than one-half of each day upon the yearly average.

II. Even during day, it is dependent upon the weather, being interfered with in its action by partial rain, storms, morning and evening mists, and those dense fogs to which our climate is peculiarly liable during the short days of winter, when, for weeks together, its use may be suspended entirely.

III. The utmost vigilance is constantly required at each station; yet, along extended lines, communications are forwarded with slowness and uncertainty, in consequence of which a degree of brevity, often objectionable, must be observed in the despatches.

IV. The symbols are publicly displayed, and their meaning thereby rendered liable to detection; a circumstance which has, on many occasions, led to the publication of the secrets of government.

The system here advanced causing expense so small as to bear no comparison with that now incurred, and effectually supplying the deficiences, and avoiding the imperfections above mentioned, offers advantages to the public, as well as to the Government, which it is hoped are not unworthy of consideration. The Electro-Magnetic Telegraph which the writer has invented for this purpose is small, compact, and portable, yet very strong in its construction; is unaffected in its action by darkness, or any obstacles of the atmosphere; the first signal being an alarum, which continues its call at intervals till answered, demands no vigilance; its action at any number of connected towns, stretching from one end of the kingdom to the other, may be considered as simultaneous, since the electric fluid traverses many hundred miles in a time too short to be appreciated; it ensures correctness in the notices given, being so arranged that each signal to be represented to others, is at the same instant, presented to the eye of the signaliser; it precludes the possibility of any but confidential clerks seeing the symbols given, and to which, when requisite, they would have no key. Lastly, as an advantage peculiar to itself, this instrument, by the instantaneous transmission of notices, sets the most broken dialogue on the some footing with a single despatch. Though not impracticable before, it may perhaps be said that, by this system, Telegraphic Dialogue is introduced.

For the execution of this plan, the only requisites are, that one of these instruments be kept at each of any number of towns, between which intercourse is to be carried on, and that two copper wires, properly defended, be laid in the earth, along the intervening line of road, by which the instruments may be connected with each other, and the telegraphic notices conveyed. Admitting the capability of the instrument, and the correctness of the principle, yet two apparent difficulties in the execution of the project will naturally suggest themselves to the reader, viz.:—

1stly. The liablity of small copper wires, extending for some hundreds of miles to receive injury; and, 2ndly, the difficulty of determining the place where such injury has been received.

Since any serious inconvenience here would, indeed, form a weighty objection against the system, it may be as well to consider how these difficulties may be effectually obviated, before proceeding further. Injury to the wires may result either from, I., a gradual decomposition of the metal; II., a fracture, owing to the partial settling of the ground; or, III., external violence—either accidental or designed.

I. Copper, as is proved by the perfect state of ancient coins, which have lain buried for ages, is subject to very slow decay, and the protecting trough, already described, by guarding the wires from moisture and air, would effectually preserve them.

II. Along old-established roads, and below railroads now forming, no settling of the old soil would occur, but, to avoid ill effects, where the soil is not consolidated, and to admit of contraction from change of temperature, the wires would be laid with a sufficient degree of laxity to allow of moderate elongation, without exerting tension on the metal, which, from its softness and toughness, is nevertheless capable of supporting a very considerable strain.

III. From external violence of an accidental nature little apparently need be feared, and it may be difficult to suppose any so great, as to form a probable cause of injury to the wires at a depth of two feet below the surface of the ground. Against such as is designed, the ordinary precautions can alone be resorted to. It may be observed of both these cases, that the road would, on a careful inspection (conducted on a plan presently to be described,) offer such marks as would immediately point out where the injury had taken place.

(*To be continued.*)

CORRESPONDENCE.

TELEGRAPH COMPANIES.

To the Editor of the Telegraphic Journal.

Sir,—A spirit of speculation has evidently overwhelmed the hitherto sedate telegraphic world. New companies are started in all directions. I have heard of eight already endeavouring to leap into existence, in addition to those already brought out within the last month. Let us pause. Telegraph property has not yet been the most remunerative. We have already one or two companies of some years' standing which have yielded no dividend; and as the ground is tolerably well occupied, the prospects of new undertakings must be a precarious one. Let the existing companies reduce their tariffs, not only in the United Kingdom, but for continental messages, then we may hope for a speedy increase in their receipts. The introduction of the shilling scale has greatly increased the use of the telegraph among the people generally, and I have no doubt but that a further reduction would lead to the most beneficial results, and would ultimately prove exceedingly profitable. With a population of 32,000,000, one message for each person in the year would yield an income, at sixpence each, of some £800,000. The enormous increase in the number of letters which followed the reduction in the postal charges of the country, points out the probability of a similar increase in the number of telegraphic messages were a low uniform charge adopted.—Yours, &c., J. L. Davis.

April 13, 1864.

To the Editor of the Telegraphic Journal.

Sir,—Much has been said in praise of Sig. Bonelli's typo-electric telegraph, especially as regards the great speed attainable; so much so, that the writers of our professional periodicals, poetically inspired, point towards the possibility of its becoming a formidable rival to the schemes of Sir Rowland Hill.

But, considering the line requires from five to nine wires, the writer of these lines can only see a retrograde movement in the adoption of such a system.

Our present electricians and telegraph engineers aim chiefly at producing a cheap well-insulated single wire line served by effective instruments; and such genii as Frischen and Siemens even have schemed out arrangements for sending messages at the same time from both ends of one wire. By working in that direction alone a saving, and, consequently, large reduction of charges may be arrived at, and not by ninefold increasing the cost of line; and, after all, only doing the work others can do with two wires, disregarding entirely the great many interruptions a line thus complicated necessarily must be exposed to; for, be it remembered, the chances against it are not merely as the number of wires, but as their combinations to one. I am here alluding to Siemens, Halske, & Co.'s typo-printing telegraph, exhibited in 1862, by which eighty words per minute were transmitted through a circuit of two thousand miles, including fifty miles submarine cable between England and France, from the Submarine Telegraph Company's offices, dispatched by gentlemen neither of whom had any practice with the instrument, or had previously seen it.

This instrument only requires one line wire and no battery. Should any company have sufficient traffic to keep it spinning night and day, they might well reduce their charges to one-tenth of the present, but not the promoters of Bonelli's: so much for the consolation of other companies.

I shall be most happy in furnishing you with a detailed description of the above instrument for one of your next numbers, so that your readers may judge for themselves how far I am right in pointing to it in preference, not alone of Bonelli's, but all other existing Roman-type printing telegraphs of the day.—I am, dear sir, yours very truly, G. R.

TELEGRAPHIC NEWS.

New Zealand.—An electric time-ball has been erected upon the roof of the custom-house at Wellington.

Telegraphy in Mexico.—The French Government are dispatching a large staff of experienced officers and engineers to Mexico, to construct extensive lines of telegraph, for which the materials are also being shipped.

Atlantic Telegraph Company.—We are given to understand that the contract of Messrs. Glass, Elliot, & Co., is not only to manufacture and submerge the Atlantic cable, but to keep the same in working order for twelve months. If we are correctly informed, this latter feature of the tender bespeaks the confidence of the contractors, and is calculated to give assurance to shareholders in the undertaking.

The Persian Gulf Telegraph.—Information has reached the India-office, Victoria-street, that the whole of the above cable has been successfully laid, and that it was in excellent working order. The message, we believe, was transmitted from Bushire via Constantinople. Sir Charles Bright has taken his departure for England, and is expected to arrive in about a week's time.

The Telegraph between Europe and America.—We understand that Her Majesty's Government have granted the concession of a right of way through British Columbia, for an electric telegraph to connect the existing United States lines with those to be extended from Russia, across Behring's Straits, a concession for the latter portion of this line having previously been given by the Russian Government to Mr. Collins, an American citizen.

Ionian Islands.—A letter from Corfu, dated 10th ultimo, says:—"A great explosion took place last evening at Fort Abraham, fifty shafts having been set off at one time by electricity. The destruction was immense; and I thank God no accident occurred. All here is hurry and bustle to be ready by the end of April, when it is expected that the King of Greece will take possession of the place. The vessels of war are busily engaged in the roadstead shipping stores, &c."

Windermere Ferry.—A great boon has been conferred on that portion of the public who for business or pleasure are in the habit of crossing this ferry. On Tuesday, the 5th instant, an electric cable, covered with copper sheathing, manufactured by Messrs. Siemens, Halske, & Co., was successfully laid across the lake, from the Nab to the Ferry House, a distance of 600 yards, communicating with a patent railway alarm-bell, made by the above firm (the clockwork of which is released by the action of a current on the electro-magnet, generated from permanent magnets), the sound of which may be heard many miles, so, in future, parties desirous of crossing from the Nab have only to press down a light lever, and the whole retinue belonging to the Ferry Hotel will instantly be informed that the boat is wanted. This will, no doubt, be the means of doing away with the delays which have been so long experienced by those in the habit of crossing, and which have in many cases been attributed to the negligence of the proprietor of the ferry, or his servants; the whole of the work was undertaken and satisfactorily completed by Louis J. Crossley, Esq., of Halifax, whose gratuitous and valuable services cannot be too highly appreciated.

Submarine Telegraphy.—The Earl of Caithness, one of the directors of the Electric and International Telegraph Company, has just made a cruise, in the company's steamer Monarch, off the east coast, from which cables have been laid to the continent. Captain Blacklock, the company's submarine engineer, went out earlier in the month, for the purpose of repairing the cable from Lowestoft to Amsterdam, and the repairs were effected in three days, although the weather was rather rough. The fault was found in thirty to thirty-five fathoms, and at a distance of about thirty-five miles from the shore. Mr. C. F. Varley, the company's electrician, assisted in the superintendence of the repairs. When the Monarch put to sea, with the Earl of Caithness on board, she picked up some buoys which had been left out, and also took up a portion of the original cable, laid by the Electric and International Company, to the Hague, in 1853. Although this cable had been submerged eleven years, the parts recovered were found in excellent condition. The line just repaired has been described as the Lowestoft and Amsterdam cable, but, strictly speaking, it should be called the Lowestoft and Zandvoost line, as it touches the Dutch coast three or four miles from the Hague. The company has also another cable, from Dermvich to Zandvoost. Each of these cables contain four wires, but the business developed with the continent has become so considerable that it is not improbable that a third line will be laid.

Continental Telegraph Line through British Columbia.—I find in one of our English journals the announcement that T. McD. Collins had recently had an interview with the Duke of Newcastle, at the Colonial-office. This interview probably had reference to Mr. Collins' projected telegraph line from Russia through British Columbia. Much curiosity is still afloat in telegraph circles touching the nature of the contract which Brutus J. Clay recently claimed to have concluded with the Emperor of Russia. It is possible that there may be certain parties in those circles who are well posted in the matter, but who, for reasons of their own, choose for the present to keep what they know to themselves. The quietness with which Collins has been operating for the past twelve months has led some people to surmise that he has really put the Russian part of the business into the hands of Mr. Clay. Since the foregoing was written I hear that letters have been received in town from Mr. Collins. He states that the object of his interview with the Duke of Newcastle had not been definitely attained, but that matters, on the whole, looked very encouraging, and he felt no doubt of ultimate success. I also hear that Mr. Clay has had nothing whatever to do in St. Petersburg with Mr. Collins' enterprise, and that there is much doubt felt and expressed as to his having had any connection with any other project of a similar nature.—*Correspondent of the Weekly British Colonist.*

A Telegraph Clerk Committed for Manslaughter.—The district coroner, W. H. Brewer, Esq., on Thursday re-opened the inquest at the Hanbury Arms, Aberbeeg, on the bodies of John Williams and William Worthing, who were killed on the Western Valley branch of the Monmouthshire Railway, on the 17th ult. The evidence having been read over to each witness, the coroner summed up, and the jury, after the deliberation of nearly half an hour, returned a verdict that the deceased died from injury received at an accident on the 17th, which accident was caused through the negligence of the telegraph clerk, James Yendoll, of the Aberbeeg station, against whom they returned a verdict of manslaughter. The coroner read the report of the inspector of the Board of Trade, who thoroughly condemned the condition of the line, and recommended that the staff system should be adopted.

Dean Clough Institute, Halifax.—On Wednesday, the 6th instant, the members and friends of this institute held their first *soirée*, in the Odd Fellows' Hall, when upwards of 500 persons sat down to an excellent tea. The spacious room had been tastefully decorated for the occasion with mosaics, banners, festoons, and fabrics of various hues, and mottoes, the whole having been carried out under the superintendence of Mr. Harry Crossley and Mr. Lochead. After tea the chair was taken by Mr. John Crossley, and a most interesting public meeting was held, no pains, trouble, or expense having been spared in catering for the amusement of the assembled guests. During the evening some excellent pieces of music were performed by a string band, and there were also present several members of the Halifax Glee and Madrigal Society, assisted by Miss Illingworth and Miss Nalton, of Bradford, and Miss Suter, of Halifax, all of whom sang remarkably well, and were much applauded. The pieces selected were as follows :—"Tramp, now tramp," "Barney O'Hea" (Miss Illingworth), "Come if you dare," "Health to my dear," "Away to the mountains' brow" (Miss Suter), "When shall we meet" (Miss Illingworth and Miss Nalton), "Market chorus," "The ship boy's letter" (Miss Nalton), and "The fisherman's good night." Mr. Stringer presided at the pianoforte. At intervals brief addresses were delivered by the chairman, the Rev. W. Roberts, the Rev. R. Harley, F.R.S., Rev. C. Clark, Rev. W. Hewgill, M.A., and Mr. F. H. Bowman, F.C.S. Mr. Roberts, in his speech, spoke of the importance of combining recreation and labour, and said he believed that play was an essential part of their life, both bodily and mental. He knew nothing more natural, more proper, and more pleasant than that they should have those entertainments, to lighten life, and to make it more comfortable. He spoke of the efforts which Mr. L. J. Crossley and Mr. E. Crossley had put forth to render the entertainment on that evening a great success, and said he did not know that they could have done anything more noble, or anything that would pay them better in personal comfort, and in the estimation of their workpeople which would be accorded to them, than of having got up such an entertainment as that. The remainder of the evening was devoted to telegraphic experiments, wires having been fixed in all parts of the room; and these were quite an attractive feature, and were well received. The working of the electric telegraph was superintended by Mr. L. J. Crossley, and between the hall and Manchester Hughes' Roman Type Printing Telegraph was used, which the United Kingdom Telegraph Company have the sole privilege of working on their lines. Then there was Sir Charles Bright's bell instrument, between the hall and Leeds; and Messrs. Siemens, Halske, & Co.'s ink writing instrument between the hall and Leeds, London, Bradford, Hull, and Manchester; also, Messrs. Cooke & Wheatstone's single needle instrument between the hall and Sheffield direct. Then there was Messrs. Siemens, Halske, & Co.'s dial instrument, and Messrs. Cooke & Wheatstone's double needle instrument from one end of the room to the other. During the evening several messages were despatched by persons in the audience to the various towns already named, and answers were in every case promptly received. One of those questions was to Leeds, and was as follows :—"Which town do you think is entitled to be considered the metropolis of the West Riding?" the answer to which was, "Why, Halifax, I should say, of course"—(laughter). During the evening Messrs. E. Crossley, J. W. Ward, and F. H. Bowman exhibited some microscopes and stereoscopes, and some galvanic batteries were also brought into full play. At the close of the proceedings Mr. Lochead moved a vote of thanks to their young employers for their kindness in getting up the entertainment, which was seconded by the Rev. J. Bottomley, of Sowerby, and carried with acclamation. Mr. L. J. Crossley, in acknowledging the compliment, expressed the obligations the meeting was under to the telegraphic clerks in London, Manchester, Leeds, and other places; and Mr. E. Crossley also addressed a few observations. The Rev. W. Roberts moved a vote of thanks to the singers, which was seconded by Mr. Diggins, and carried amid loud applause. Mr. Hoyle moved a vote of thanks to the chairman, which was seconded by Mr. N. Thompson, and carried with enthusiastic cheering. The proceedings were brought to a termination by the singing of the National Anthem. The following is an abstract of the report of the institute for the year ending March 31st, 1864 :—In the news-room there were six daily and eleven weekly newspapers, and two quarterly and ten monthly periodicals. The library contains 2,526 volumes. The number of issues in the special department had been 325, and the number of magazines 690. There had been five public readings, and three lectures, and the average attendance had been 150. The present number of members was 480, whereas last year it was only 285.

MISCELLANEA.

It is curious to take a retrospective view of the mode in which the effects of the Leyden phial were announced to the world on their first discovery. The philosophers who first experienced in their own person the shock attendant on the transmission of an electric discharge were so impressed with wonder and with terror by this novel sensation that they wrote the most ridiculous and exaggerated accounts of their feelings on the occasion. Muschenbrook states that he received so dreadful a concussion in his arms, shoulders, and heart that he lost his breath, and it was two days before he could recover from its effects; he declared also that he should not be induced to take another shock for the whole kingdom of France. Mr. Allemand reports that the shock deprived him of breath for some minutes, and afterwards produced so acute a pain along his right arm that he was apprehensive it might be attended with serious consequences. Mr. Winckler informs us that it threw his whole body into convulsions and excited such a ferment in his blood as would have thrown him into a fever but for the timely employment of febrifuge remedies. He states that at another time it produced copious bleeding at the nose; the same effect was also produced upon his lady, who was almost rendered incapable of walking. The strange account naturally excited the attention and wonder of all classes of people, the learned and the vulgar were equally desirous of experiencing so singular a sensation, and great numbers of half-taught electricians wandered through every part of Europe to gratify this universal curiosity.

Faulkner's Electric Signals.—These signals are so constructed as to give the winding signal from the surface to the bottom, and return signal from the bottom to the surface of the shaft, and also for signalling on the levels or inclines by touching the part of the signal constructed, either a greater or lesser number of times, as may be arranged. This will be found to save much inconvenience to the men working in the pit. The signals will also be found useful for warning the men to commence or cease work, by so many rings of the signal, which will be heard all over the pit. It is also adopted for ventilating doors, to indicate whether they are open or shut. For instance, if a ventilating door which ought to be shut is, by neglect, left open, the signal is so constructed upon a self-acting principle that it will ring off any number of hands with a tremendous noise until the door be closed. By a singular arrangement, if a door which ought to be open is by any means closed, the signal will also ring until it is opened. If the door is only open one-sixteenth of an inch it will set the signal at work with as great a noise as if it were left wide open. In order to show from what part of a mine a signal proceeds a box or partition may be fixed in some conspicuous place, with a number-plate and a number for each part of the pit which it may be desirable to indicate. These number-plates are fixed by hinges, so as to move in or out, and the electric wire is fixed to each number-plate corresponding with that part of the mine which it represents. Thus, when a signal is rung, the number of the part from whence it comes is projected outwards. This invention, in fact, may be used for any purpose of warning, or calling, or signalling in the pit; and it is to be observed that when any signal is touched it can be distinctly heard all over the mine.

Meteorology.—The following interesting results of the ascent of Messrs. Glashier and Coxwell will be read with interest:—Mr. Coxwell had been watching the weather all day; and once during a break in the lower clouds he had sent up a pilot balloon, which had moved towards the east when at a high elevation, and, connecting this with the current we had met with, he began to fear that the railway we had heard might be the Southend Railway, and if so we were drifting out to sea. He, therefore, determined to take a dip downwards without delay, before attempting a higher elevation, so that if we found ourselves over the water we might have gas enough to keep us up for some time. We began to dip downwards. The sky continued of a deep blue, the air free from mist, and the sun hot till we approached the height of 7,000 feet, and at 6,000 feet we lost sight of the sun, and were in dense white cloud at 5,500 feet; when at 3,000 feet fine rain fell, and we caught sight of the earth at the height of 2,500 feet. We expected to find ourselves over Essex; but hills and a beautiful undulating country presented themselves, and it was evident we were at fault. Mr. Coxwell then decided upon anchoring, and we did so on the outskirts of a pine plantation, near Sevenoaks, in Kent, on the estate of the Marquis of Camden, and we found the direction of the wind here south-east, the same as that at starting. The temperature of the air was 46 deg. on leaving; at the height of 1,000 feet it was 41½ deg.; at 1,500 feet it was 40 deg.; at 2,000 feet 37 deg.; at 3,000 was 32 deg.; from 3,500 to 4,000 there was no variation from 32 deg.—this was the lowest temperature met with; at 5,000 feet the temperature increased to 36 deg., and did not change for 500 feet, then decreased to 34 deg. at 6,500, at which point it turned to increase, amd was 40 deg. at 8,000 feet; it decreased to 34 deg. again at the height of 9,000 feet; it then increased on leaving the cloud below to 36 deg. at 11,000 foot, and rapidly to 46 deg. whilst between 10,000 and 11,000 feet high. The highest temperature observed was at 8,000 feet in descending, when it was 47 deg.; from this point the temperature declined, on descending, to 40 deg. at 1,500 feet high, being nearly the same as on ascending, and to 46 deg. on the ground. The temperature of the dew point, or that temperature at which water in the invisible shape of vapour is deposited as water on substances of that temperature, was 7 deg. below that of the air on leaving the earth, and this difference was the same up to 2,000 feet; it then decreased to 1 deg. on entering the cloud, and was 1 deg. to 3 deg. whilst in the dense cloud; on leaving it at 8,000 feet this difference suddenly increased to 10 deg., and varied from 14 deg. to 24 deg. between the heights of 8,000 to 11,000 feet, and decreased on again entering the cloud to 5 deg. and 6 deg. There were 2¼ grains of water in a cubic foot of air near the ground, and about 2 grains in the cloud, and about one grain only above the cloud. The humidity of the air, therefore, increased from the earth to the centre of the cloud, where it was all but saturated, and decreased rapidly above the cloud where it was very dry. No ozone was detected by Schonbein, Moffat, or Lowe's test papers, during the time the balloon was in the air. The lines of the solar spectrum were very numerous and well-defined; the spectrum itself was very long.

PRICES CURRENT OF INSULATING MATERIAL.

Gutta Percha, as imported.

Genuine mixed, first and second qualities.....	2/3 to 2/6 per lb.

TO CORRESPONDENTS.

We shall endeavour to maintain strict impartiality in all matters relating to the great interest we seek to represent. Our columns are at all times open to fair criticism. The communications of "A Deluded Shareholder," "Dividend," and "Irving S. Taylor," are inadmissible, as containing unjustifiable insinuations against the public and private characters of individuals filling positions of the highest importance in connection with a great national undertaking. It appears to us somewhat presumptuous on the part of our correspondents to pass such sweeping condemnation upon the conduct of a great Company and its scientific advisers, who have pursued one steady and sensible course, by subjecting various improved materials and cables to experimental tests, and have selected those which they considered the best for the object in view.

Alpha.—The Directors of the United Kingdom Telegraph Company consider Hughes' system superior to Bonelli's.

E. W. M.—The invention to which you refer is Bakewell's.

As information respecting Improvements, Extension of Lines, and Progress of New Undertakings will at all times be most acceptable, we hope that our readers will kindly render us assistance in our efforts to establish a Journal worthy in all respects of the great interest it seeks to represent, by furnishing us with brief notices of events and occurrences in connection with Telegraphy.

Communications intended for publication must be authenticated by the names and addresses of the writers; not neccessarily for insertion.

Letters relating to Advertisements are to be addressed to the Publishers. All other letters and communications to be addressed to the Editor of the *Telegraphic Journal*, 5, Suffolk-lane, Cannon-street, London, E.C.

The *Telegraphic Journal* can be had of Messrs. Smith & Co., Strand; Messrs. Dawson & Co., Cannon-street, E.C.; Messrs. Kent & Co., Paternoster-row, London. Messrs. Heywood & Co., Manchester; at the various railway stations; and of all news-agents, &c., &c.; or it can be supplied, if preferred, direct from the Office on the following terms:—

	s.	d.
Quarterly	4	4
Half-yearly	8	8
Yearly	17	4

TO ADVERTISERS.

The *Telegraphic Journal* is the most effective medium for inventors, patentees, contractors, manufacturers of insulating materials and electrical apparatus to submit their various specialities to the consideration of secretaries and managers of telegraph or railway companies, and other persons engaged in electrical and telegraphic pursuits.

Clerks, assistants, manipulators, and instrument makers, seeking employment, &c., will find the *Telegraphic Journal* a ready means of making known their requirements.

Advertisements must be delivered to ensure insertion before Seven o'Clock on Thursday evening in each week. The charges for Advertisements are—

	£.	s.	d.
Whole page	4	4	0
Half ditto	2	10	0
Quarter ditto	1	7	6
Four lines and under (single column)............	0	3	6

Single Advertisements from the country must be accompanied with stamps in payment.

ON THE APPLICATION OF ELECTRICITY TO DOMESTIC PURPOSES.

By William Henry Preece, Assoc. Inst. C.E.

(*Continued from page* 184.)

2. *The Wire.*—Having thus described the construction and action of the battery, we have next to consider the means employed to convey its influence to the bell. This is done by metal wires. There are some materials which readily allow the passage of electricity through them, while others offer a stout opposition to its course. The former class of bodies are termed *conductors*, the latter *insulators*. All the metals, charcoal, saline solutions, water, moist animal substances, the human frame, are conductors. Shellac, sulphur, resins, gutta-percha, caoutchouc, silk, glass, and most dry organic and vegetable bodies are insulators. There is, however, no absolute line of distinction between these two classes of bodies. There is no such thing as perfect insulation or perfect conduction. The two terms imply a difference of degree only. A bad insulator is a good conductor, and a bad conductor is a good insulator. There are many materials which occupy a neutral position which are difficult to define as belonging to either class. Every substance offers a certain resistance to the passage of the current. When this resistance is very small, as in the case of a metal wire, we have a conductor; when it is very great, as in the case of silk, gutta-percha, or india-rubber, we have an insulator. Hence, the conductor employed in dwellings is copper wire coated with an insulating substance such as india-rubber, gutta-percha, cotton steeped in some insulating solution, or even plain cotton alone. It is thus coated to maintain the current in its proper course, and prevent the various wires from becoming wet, or from coming into contact with each other. The wires conduct the current as water-pipes convey water or gas-pipes gas, and if we destroy the insulation by allowing them to touch each other, or to come into contact with wet, they would act the same as leaky pipes, and allow all the current to escape, and therefore prevent us from producing any sound upon the bell. The wires are employed in this way:—If we require to ring the bell, B (Fig. 5), it is necessary to take

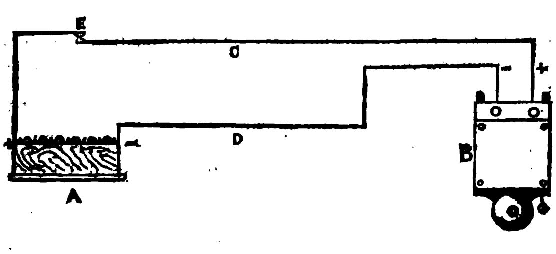

Fig. 5.

a wire, D, from one pole of the battery—say the negative pole—to one terminal of the bell, B;—the connecting thumbscrews of electrical instruments are called *terminals*. Another wire from the other pole is taken to E, the spot or room from whence the bell has to be rung, and from thence the wire, C, is carried to the other terminal of the bell.

It will thus be seen that when the two ends of the wire at E, which are maintained separate, are brought into contact, the "circuit" is completed, the battery is brought into play, the force is generated, the current flows, and the bell rings. The wire, C, is termed the *main wire*, and the wire, D, the *return wire*. It is not necessary that there should be a separate battery and a separate return wire to every bell: the same battery and return wire will answer for any number of bells; but this point will be subsequently more clearly illustrated.

The simplicity of this arrangement, and its advantage over the existing system, is that the wires can be led anywhere, under the paper, behind the skirting, or between the joists. They are never likely to be injured, unless they be broken by some repairs to the house. They should, however, never be fixed where wet is likely to reach them, unless they are well insulated with gutta-percha or india-rubber. Such an accident as a broken wire is at once shown by the bell attached to that particular wire ceasing to ring, and it is very easily rectified by twisting the broken ends together temporarily. A permanent joint should subsequently be carefully made, and always *soldered*. Soldering is essential in completing all joints of wires, even in private dwellings, in our damp climate; for if they be not done so, the natural moisture of the atmosphere is certain in time to produce oxidation upon the surface of the wire at the point of juncture, and thereby want of perfect electrical continuity in the wire. This would produce feebleness in the sound of the bell, and lead one to imagine that the battery was failing when it was really in full action. Failures and imperfections in telegraphy are frequently attributed to the battery or the instrument, when the true cause of trouble lies in improper or careless jointing. In damp positions and moist climates too much attention cannot be devoted to the perfection of joints.

It is not essential that the wires in the interior of a house be carefully insulated. The French use plain cotton-covered wire. But in England, where the climate is so much damper, some more insulation is advisable. It is sufficient if the cotton be steeped in a solution of caoutchouc or other insulating material. In out-of-door work, however, such as between the house and the stable or the lodge, high insulation is imperative. Gutta-percha-covered wires, properly prepared with tape or hemp saturated with Stockholm tar, will be found the best, and it is generally found advisable to protect them with pipes or some external protecting wire, and bury them at least eighteen inches deep under ground. Where practicable it is, however, preferable to use suspended wires; but as they are unsightly, they are generally objected to. Where sightliness is of no consideration, and where length can be obtained, it is easy to stretch a thin iron wire in one span of 400 or 500 yards. This is infinitely cheaper and far more durable than underground work.

3. *The Buttons.*—The apparatus employed to bring the two

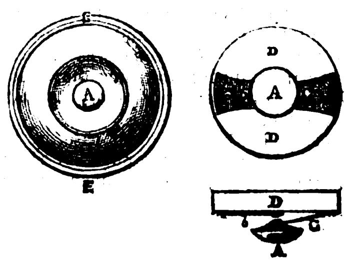

Fig. 6.

ends of the wire at E (Fig. 5) into contact is very simple. It is called *a button*.

D is a disc of wood, shown in plan and elevation to the right of the figure, upon which is fixed a small plate of brass, *b*, and to which is fixed a hardened brass or steel spring, *c*. The ends of the wires at E (Fig. 5) are soldered to *b* and *c*. An ivory button, A, which receives the pressure of the finger, is fixed to the end of the spring, *c*, which it presses into contact with the plate, *b*. The circuit is thus completed, the current flows, and the bell rings. In order to ensure perfect electrical contact between *c* and *b*, their ends are tipped with platinum or silver, which do not oxidize nor get dirty. The whole is protected by a box of wood or porcelain, E, having a hole in the centre to allow the ivory knob to be exposed, and which screws upon the wooden disc, D. It is shown complete to the left of the figure. The button is fixed to the wall or piece of furniture by driving two screws through the disc, D, before the top is screwed on.

The covering, E, should be occasionally unscrewed, and the points of contact scraped and cleaned. If they get dirty the current may fail to flow, and the bell fail to sound. The correct working of nearly every electrical instrument depends upon the care with which the points of contact are maintained clean. Strong currents of electricity invariably dirty to some extent the points of contact, even when they are silvered or platinized; but any harm resulting from this effect is greatly reduced by producing a rubbing contact by means of springs. When two pieces of metal are forced into immediate contact without any motion over their respective surfaces, they are said to be brought into *dead contact*, but when one metal moves to the smallest extent over the surface of the other it is said to have a *rubbing contact*. A rubbing contact removes any dust or dirt that may have accumulated on the points of connection. This is effected on the button by the spring, *c*, which rubs to a small but sufficient extent the plate, *b*. If not cleaned occasionally the dust may, however, accumulate so much as to master the effects of this rub.

The spring, *c*, may break from improper hardening, or the introduction of impure material. Springs, though most carefully selected, will sometimes fracture. This accident is, however, very remote, but its probability must not be overlooked. It can only be rectified by the insertion of a new spring or a fresh button. Spare buttons should be kept, to be prepared for such contingencies. In the last form of spring introduced by the French manufacturers this liability is reduced, by giving it a curved or spiral form, which increases the length of the spring, and thereby spreads the motion over a more extended surface.

It will be easily seen that these buttons can take any form to suit the particular locality in which they are placed. They may be made to act by a pull, instead of pressure, for a hall door. They may be constructed like a pair of nippers, to be placed under the pillow. They can be fixed under the tables to receive the pressure of the foot. Indeed, as they are required simply to bring two pieces of metal together, they can be made of any shape and for any purpose.

4. *The Bell.*—We have next to consider the bell—to comprehend the action of which it is necessary to explain briefly the magnetic properties of electricity. The influence of a magnet on iron or steel is too well known to need comment; but the action of an electro-magnet is not quite so well understood. If we take a piece of soft iron, and wind around it carefully and neatly a quantity of copper wire, covered with silk, to prevent one lap of wire from coming into contact with another, and then join the two ends of this wire one to either pole of a battery, so that the current may flow through the wire, and round the iron core, we shall find that the core has become a magnet, that it will attract iron and steel, that it is, in fact, an electro-magnet with all the powers of an ordinary magnet. This power, however, only exists during the time the current flows. The moment the current ceases all attractive power stops. Thus in Fig. 7, when a current is transmitted through

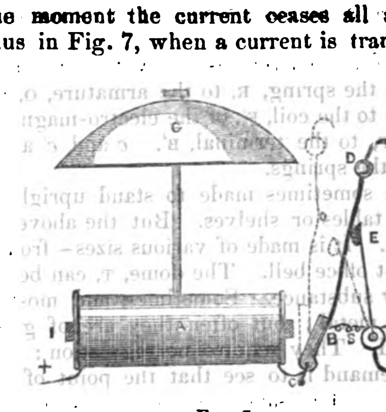

Fig. 7.

the electro-magnet, A, the iron core, I, becomes a magnet, the soft iron armature, B, is smartly attracted, the hammer, D, strikes the bell, C, and sound is produced. The moment the current ceases the hammer falls back by the action of the spring, S, and is prepared for another blow. Each current sent produces one blow on the bell. The above is a description of any direct-action electrical bell, but the French bells—"*trembling bells*," as they are significantly termed—are varied in this way:—The main wire which passes through the coil, A, is connected to the armature and hammer rod, B, which rests against a spring, E, in contact with the other end of the wire (—). Now, when a current flows, the armature, B, is attracted; the bell is struck, and therefore sounds; but the circuit being broken at E, the current ceases, and the hammer falls back again. The circuit is again completed at E, the current again flows, the armature is again attracted, and the bell is again struck, and again the circuit is broken, and the hammer falls back. These makings and breakings, attractions and fallings back, occur as long as the button is kept down, and the current flows. The result is a rapid trembling ringing of the bell, which is very effective and very singular. It ceases when the button is released and the current stopped.

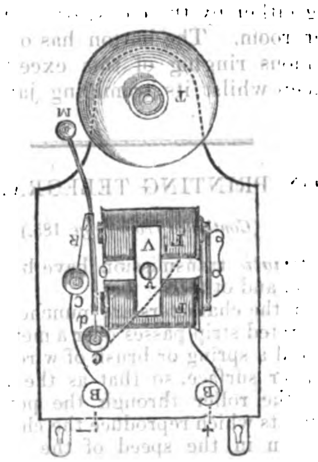

Fig. 8.

The above figure (Fig. 8) represents the ordinary French bell which is made to be attached to the wall by two screws or nails. Its action is precisely similar to that of Fig. 7. The current passes through the electro-magnet, FF′, the armature, O, is attracted, the bell is struck, the circuit is broken at R, the hammer falls back by the elasticity of the spring, *d*, contact is again made, the current again flows, the bell is again struck, and so on, rapid makings and breakings of the current take place, which produce the trembling movement of the bell.

The piece, V, keeps the electro-magnet in its position by means of the screw, v.

The course of the current is easily traced. It enters at B, passing through the spring, R, to the armature, O, to spring, d, and from thence to the coil, F′, of the electro-magnet, and out at the other coil, F, to the terminal, B′. c and c' are simply the studs that hold the springs.

The bells are sometimes made to stand upright, as Fig. 6, to be placed on tables or shelves. But the above is the most convenient form. It is made of various sizes—from a loud hall alarum to a light office bell. The dome, T, can be made of any note, and of any substance. Sometimes, and most frequently, they are of bell metal; but often they are of glass, and frequently of wood. They require no regulation; and the only attention they demand is to see that the point of contact, R, is maintained clean. The same remarks apply to this point, as I have previously given to the points of contact of the buttons.

These bells, as I have described them, ring only during the time the button is pressed down; but it requires the addition of a very simple piece of mechanism to make them ring continuously, from the instant a momentary pressure is exerted upon the button, until the attendant who is summoned by the bell stops it himself. With the above bell a little instrument is required, which, on the attraction of an armature, brings into play what is termed a "local" or independent circuit, which continues to ring the bell until it is mechanically broken; but there is a very ingenious bell by M. Ragon which accomplishes this of itself. The main current, passing through one coil of the electro-magnet, releases a detent that falls and completes a local circuit, which actuates the other coil of the electro-magnet, and by this means works the bell continuously, until, in fact, the detent is mechanically raised and restored to its original position by the attendant whose attention is required. Such a bell is an admirable alarum. It can be rung by a clock at any hour required, and will continue to ring until the drowsy sleeper is awakened. It is an admirable contrivance to fix in the servants' sleeping apartment, and rouse them up at the proper hour. Housekeepers will know its value. It can be set going either by the clock, or by the housekeeper in person, from her room. The button has only to be touched to start the continuous ringing of this excellent alarum. It is impossible to sleep whilst its trembling jar beats continuously on the ear.

ON PRINTING TELEGRAPHS.

(*Continued from Page* 185.)

Methods of *automatic* transmission have been invented by Bain, Allan, Wheatstone, and others.

In Bain's system the characters are punched out from a strip of paper. The perforated strip passes over a metallic roller connected to the line-wire, and a spring or brush of wires fixed to the battery presses on its upper surface, so that as the paper moves forward the wire touches the roller through the perforations, sending a succession of currents which reproduce the characters at the distant station. A variation in the speed of the two machines simply alters the lengths of the signs, without in any way confusing the message. This system was worked some ten years since between Liverpool and Manchester, at a speed of about seventy words per minute; but owing to the defective insulation of the wires at that period, and the difficulty of punching the paper by the imperfect apparatus employed, it was discontinued.

Professor Wheatstone has now perfected an automatic telegraph, founded upon the same principle, which bids fair to be very successful, and admits of a vastly increased speed. In Professor Wheatstone's system the dashes of the Morse alphabet are represented by dots placed on the right hand of the paper ribbon, and the dots by similar marks on its left. Another line in the centre of the ribbon serves to form the spaces between the letters and words. This arrangement permits the perforating apparatus to be very much simplified, and to be manipulated with comparative ease. The apparatus by means of which the punched slip transmits the message is on the principle of the Jacquard loom. In it three wires are placed in a position precisely similar to that of the punches in the perforating apparatus. They lie on the edge of an eccentric wheel, which at each revolution presses them against the paper ribbon. If a hole be opposite the punch, it passes through it, touching the metal wheel and putting the battery in action. One wire sends positive, the other negative currents, which act upon separate electro-magnets in the receiving instrument, so as to reproduce the signs in ink.

It is obvious that a similar effect can be obtained by etching the Morse characters upon a plate of metal covered with varnish, or by writing them in insulating ink upon a piece of metallic foil or silvered paper; and by chemical decomposition, Roman letters, or even a sufficiently bold handwriting, may be copied from the foil upon a sheet of prepared paper, by ruling a series of lines across the two with metallic pencils, connected with each other and with a battery.

When the sending pencil is drawn across that part of the foil on which nothing is written, and which therefore conducts uniformly, the receiving pencil will produce a straight line upon the moistened paper; but when the sending pencil moves across the *writing*, the current will be cut off by the insulating ink, producing corresponding breaks in the line formed by the other pencil; if the two pencils are so connected as to be capable of being moved uniformly over their respective sheets, and if a series of parallel lines be drawn closely together by them, they will form a copy of the original in a species of line engraving or etching.

Many years since Mr. Bakewell invented a copying apparatus founded upon this principle, by which fac-similes of hand-writing were transmitted from London to Brighton as early as 1848.

The so-called Pantelegraph of the Abbé Caselli is really worthy the name it bears, for it transmits Chinese or Persian characters as readily as our ordinary letters, and reproduces a correspondent's autograph, or even his *portrait* if required. The despatch is written in ordinary ink upon silvered paper, and by a peculiar arrangement of batteries the copy is produced in blue upon a white ground.

The practical difficulties of the system, simple as it may have seemed from the foregoing description, are very great. It is of course necessary that the markers at the two stations shall move with perfect uniformity, as if connected firmly together. The slightest difference in the speed of the two would be fatal. The colour is apt to run on the damp paper, and as the current on a long wire does not cease at the moment at which battery contact is broken, the marks as received are apt to be rather longer than those of the original, so as to merge one into the other.

The apparatus at all the stations is precisely similar. A massive iron frame carries a pendulum about six feet long, having a very heavy iron bob, whose movements are controlled by electro-magnets, which attract it at each oscillation and hold it fast until the current which magnetizes them is cut off by a regulator clock, the going of which can be controlled with the greatest nicety without stopping it. The large pendulum, whose beats exactly correspond with those of the regulator, gives motion to two curved tables, one on each side, on which the prepared paper or original despatch is laid. The metal tracers or pencils are fixed above these tables in such a manner that they pass over the paper as it moves, ruling a line at each vibration of the pendulum. The pencils are connected with screws, which move them the ninetieth of an inch between each vibration, so as to rule a series of lines a ninetieth of an inch apart. They cannot be arranged so as to pass over the paper in both directions without tearing it, and are therefore lifted alternately. To avoid loss of time from this arrangement two despatches are transmitted at the same time, one while the pendulum swings to the right, the other while it moves to the left. The clocks at the two stations are kept in perfect accord by altering their rate during the progress of the transmission, in such a manner that a straight line which is ruled at the edge of the original despatch shall be reproduced on the receiving-paper.

In Caselli's system the synchronism of the two sets of apparatus in correspondence must be *perfect;* and as only the ninetieth of an inch of the despatch is traced by one movement of the pencil, its transmission is not very rapid. Only one line-wire is required.

In the telegraph now working between Liverpool and Manchester Bonelli uses a sufficient number of pencils, arranged in

form of a comb, to copy the whole despatch by a single movement, and thus not only saves time, but, as perfect synchronism is unnecessary, avoids the necessity for elaborate arrangements for regulating the speed of the apparatus. On the other hand, each separate pencil must have a *distinct* wire, perfectly insulated from the rest, so as to reproduce only that part of the drawing or message over which it passes. Thus, originally, when it was proposed to produce elaborate copies like those of Caselli, an enormous number of wires were needed. This idea was subsequently abandoned, and the number of wires reduced to eleven, and lastly to five. The message is set up in ordinary type, and is placed upon a truck moving upon a miniature railway. The chemically-prepared paper is laid upon a metal plate, carried on a similar truck. Over the truck carrying the type is fixed a species of comb the width of the letters, having five teeth, arranged in such a manner that when the carriage moves the comb shall pass over the face of the type so as to touch their raised surfaces; and over the truck at the distant station is a similar comb, with the same number of teeth, resting lightly on the prepared paper. Each tooth of the combs is connected by a separate and insulated line-wire, so that when any one of the teeth of the sending-comb touches a part of the type a current is transmitted, which produces a corresponding mark upon the prepared paper.

The trucks are started at the same moment by the release of detents connected with electro-magnets, and are drawn forward by weights.

When all the five line-wires are in good order the system admits of marvellous rapidity, and legible despatches may be forwarded even when they are partially deranged.

As the blue mark of Bain and Caselli is produced by the dissolving away of the iron pencil, the ferrocyanide solution is not applicable to Bonelli's system, for it is necessary the teeth of the comb should wear equally; the teeth are therefore formed of platinum, and the solution is nitrate of manganese, which does not act upon the platinum.

The inventors of the automatic systems consider that messages may be prepared by the sender himself at his own office, and handed to the Telegraph Company simply for transmission. It may, perhaps, be doubted whether merchants or their clerks will give sufficient attention to the preparation of the punched ribbon, or write so distinctly on the Caselli tablets as to produce a good working copy; so that it may always be necessary that the staff of the telegraph should prepare the messages for transmission. Still the advantages of the system are obvious. The capacity of each wire is vastly increased; and as there need be no limit to the number of clerks employed in the preparation of and the translation of the despatches, the rapidity of transmission may be urged to the furthest. Machinery preserves its superiority to hand-labour even in telegraphing.

There is a limit to this rapidity. Induction lengthens the duration of each current, tending to connect the separate signals into a continuous line: and a contact of very short duration, unless aided by a powerful battery, is insufficient to charge the wire. These effects are not very apparent in short distances, but increase rapidly with the length of the line. It seems to us that, although greater accuracy may be attained, the telegraph service will not be as *regular* even as at present if fast automatic systems come into use. The wires will always be subject to derangement; and supposing the work done by each wire is doubled, the stoppage of a single wire will delay double the number of messages.

For the public, the *safest* apparatus is that which employs one wire only, and which works at a low speed. The cheapening of rates, however, will not permit the profitable use of such a system, and certainty must be sacrificed to price.

The value of a particular system must be estimated, not by the beauty or the singularity of its effects, but by pounds, shillings, and pence; that is, its cost, the expense of working and maintenance, its speed, correctness, and freedom from derangement. Every system has its own special causes of error and its own special faults, which are not always those which unprofessional persons would suspect, although, perhaps, on no subject do the ignorant give opinions more freely or with more confidence.

So much attention is now given to telegraphy, and so much talent is devoted to its improvement, that it is difficult to imagine what the next ten years may produce. The apprehension of Tawell was in its day a wonder; but how inefficient the power of giving a verbal description of the murderer, compared with that of forwarding his very portrait!

SISSLING'S ELECTRIC BAROGRAPH.

The chief novelty in this invention consists in the employment of electro-magnetism, to register the movements of the barometer and other meteorological instruments. This object is attained in the following manner:—

A hollow drum or cylinder, working upon a horizontal axis, is propelled step-by-step by means of a forked lever carrying an armature, which is alternately attracted and repulsed by an electro-magnet in its rear, and thus gives motion to a ratchet-wheel (containing twenty-four teeth) on the axis of the drum, propelling the latter forwards as often as the electric current is passed through the magnet. A spiral spring assists the armature in recoiling from the magnet, and it is in this recoil that the motion is given to the ratchet-wheel; for the forked extremity of the lever is so constructed, that when the armature is attracted, the tongue of the fork passes over the tooth of the wheel without producing any effect upon the latter; but when the current ceases, and the armature recoils, the other tongue of the fork, catching under the tooth of the ratchet-wheel, propels the drum forwards. A pointer is attached to one extremity of the axis, on the outside of the case containing the instrument, which, passing round a dial by the revolution of the drum, indicates the hour. Above the vertex, or fore part of the circumference of the drum, a brass or ivory slide is placed, one end being attached to a small support in such a manner as to admit of a free motion being given to the other extremity in a vertical direction. The free end of the slide is continued through a small upright slot at the extremity of the drum, where it is acted upon by a second electro-magnet smaller than the first, but working with the same wire. Along the major part of the length of this slide runs a slot, in which the writer is made to slide with the greatest freedom. This writer is composed of ivory, or other light, smooth substance, and being perforated in its centre, a minute ivory screw is inserted, the lower end of which carries a crayon point, which, when the current passes, and the small magnet attracts the slide, impresses a mark upon the paper of the drum.

The barometer, whose indications the instrument is intended to record, is placed at the side of the case containing the machine. From the float in the cistern of the barometer the motion of the column is communicated by a silken cord to the circumference of an extremely light ivory wheel, and from thence by a second cord to the writer before mentioned, thus converting the vertical motion of the barometric column into the horizontal one of the writer.

To the ordinary time-piece of the observatory is attached a simple commutator arrangement; so that on the completion of every hour a battery current is sent simultaneously through the magnets, and while the armatures are attracted, the tongue of the forked lever, as before stated, passes over the tooth of the ratchet-wheel, producing no motion of the latter; at the same time, the slide being attracted by the smaller magnet, the writer impresses a mark indicating the height of the barometric column upon the paper slip on the surface of the drum. The next instant the current is broken; and while the slide resumes its original position, the forked lever in its recoil propels the cylinder forwards, and thus the instrument proceeds registering hour by hour the indications of the barometer, and checking itself, as it were, by means of the pointer and dial; for by comparing the indicator of the latter with a watch or other time-piece, it may be at once seen whether the instrument is working correctly.

By the employment of electro-magnetism the inventor (Mr. W. Sissling, of Nottingham) is enabled to dispense with the usual clockwork arrangement, till now in use in registering instruments of this kind, thus greatly diminishing their first cost, while the greater simplicity of arrangement reduces the risk of getting out of repair to a minimum. The advantage is not so apparent when only one instrument is in use, because even this register requires a time-piece to act as commutator; but it will be seen that the wires from the magnets may be conducted to any number of these instruments compatible with the maximum power of the battery employed, and the commutating time-piece need not occupy the same room, or, indeed, the same building, but may be any distance from the instruments within the same limits, while the ordinary registering barometer requires a peculiar adaptation of clockwork for every separate instrument.

The barometer is the only instrument at present worked with these registers; but the inventor is actively engaged in rendering them applicable to many of the instruments in common use in the

observatory, and will not fail, as soon as success crowns his efforts, to give the public the benefit thereof. Mr. Sissling, being actuated by no other motive than the general good, has thrown open his invention unreservedly, and will be happy to render every information in his power concerning those minute details which cannot be conveyed within the limits of a paragraph, and places his address at our disposal for that purpose.

THE INTERNATIONAL EXHIBITION, 1862.

(Continued from page 188.)

E. Tyer, London (United Kingdom, 2,977), in the apparatus exhibited by him, uses only two visible signals, "train on line" and "line clear." He uses a bell or gong in connection with these signals in the manner presently to be described. Each of Mr. Tyer's receiving instruments has two pointers or needles, one black and the other red. Each of these can point to the right, where the words "line clear" are written, or to the left, where "train on line" is written. The red pointer shows the last signal sent, the black pointer the last signal received. Each instrument is provided with two sending buttons or keys side by side; that to the right sends the signal "line clear," that to the left "train on line." These two buttons also sound the bell or gong at the far station. Mr. Tyer's system requires that this shall sometimes be done without altering any of the pointers. To effect this the button which corresponds to the last signal sent must be pressed. An intermediate station has two of these instruments, one to communicate down the line, and the other up. The terminal stations have each only one instrument, the black pointer of which refers exclusively to the line of rails on which the trains run *from* that station. An example will best show the working of Mr. Tyer's system.

Let us suppose three consecutive stations, A, B, and C, with the down line running from A to C, and the up line, therefore, from C to A. A passenger train leaves A by the down line. The signalman at A must at once inform B by striking his gong twice. He could do this by pressing either button twice, but he must take care to use the button below the end of the red pointer, otherwise he would alter the pointer at B, which is not his object. When B hears the two beats on his gong, it is his duty to answer by pressing his left-hand button ("train on line"), which moves A's black needle and B's red needle both to the left, showing "train on line." A cannot alter this signal, and it is his duty to let no train start until B, on the arrival of the train, sends him a signal "line clear," which moves A's black needle to "line clear," as also B's red needle. When the train starts from B to C, B informs C of it by two beats on *his* gong; C answers by moving B's black *down* needle to "train on line," and B must allow no train to pass on the down line till C again puts B's black needle to "line clear." C has no black needle for the down line, for when the train is present he requires no warning that the down line is blocked.

The signals for the up train starting from C are exactly similar to those for the down line starting from A, except that a bell is used instead of a gong to prevent confusion. A has no black needle for the up line, but the red needle at A refers exclusively to the up line, and always corresponds in position to the black needle at B, from which the train is coming up. It thus shows at A whether the up line is blocked or open at B. In fact, the black needles always show the condition of the line on which trains run *from* a given station, and the red needle the condition of the line on which trains are running *to* the same station. The black pointer can only be altered in position by the distant station, but the red pointer can be moved at will in its own station. When A calls B to tell him that a down train is starting, he must take care to press the button which is under the end of the red pointer, otherwise he would alter the pointers as well as sound the gong. Thus, for one and the same signal, sometimes one and sometimes the other button should be touched, which to the writer seemed rather confusing. The system is, however, in extensive use, and the motion of the red pointer would attract the man's attention to any mistake he might make.

Mr. Tyer's system has one great merit. No man can alter the signal at his own station respecting the trains which have left it, and are between it and the next station. The black needle stands inexorably at "train on line" until the station in advance alters it. It is true that this alteration may be made accidentally from the other station, but it cannot be made wilfully at the station itself.

The connections are very ingeniously arranged, so that one line suffices for all signals between station and station. When the sending buttons are left untouched, the line is connected to the coils of the black needle, and thence through the bell coils to the earth. The batteries of that station are quite disconnected from the line. A signal current arriving along the line will then move the needle or not, according to whether the sign of the current corresponds or not to the previous position of the needle, but it will always sound the bell. When one of the buttons is pressed, it first presses back a spring, disconnecting the line from the black needle coils; it next brings the line into connection with, say, the positive pole of a battery, and at the same time connects the other pole of the battery to earth through the red needle coils. A positive signal is thus sent through the line, which does not move the home black needle or bell, but passes through the home red needle coils. If the other button be pressed, it equally breaks the contact between the line and the black needle coils, but puts opposite poles of the battery in connection with the line and earth through the red needle coils. The second button, therefore, sends a negative signal along the line, and passes an opposite current through the red needle coils to that given by the first button. All these contacts are made in a perfectly simple and direct manner.

Mr. Tyer's receiving instrument for the visible or needle signals is peculiar. His pointer is a little soft-iron needle hanging from an axis in the centre of a straight soft-iron electro-magnet, round which the received current passes, magnetizing the soft-iron core, and by its influence converting the little pointer into a north or south pole, according to the direction of the current. A little below the electro-magnet is a permanent horseshoe magnet, with the faces of its poles in a plane a little behind the soft-iron pointer, and with one pole—say the north—a little to the right, and the other, or south pole, to the left of the axis of the electro-magnet. Now, if a positive current be passed round the electro-magnet, converting the needle into, say, a north pole, it is strongly repelled by the north, and attracted by the south pole of the permanent magnet, and therefore either it is deflected to the left or remains in that position if it were there already; a negative current, on the other hand, will either move the needle to the right or maintain it there. When no current is passing, the little soft-iron pointer or needle simply remains in the position in which it was last placed, owing to the attraction which, in its unpolarized condition, it experiences from either pole of the permanent magnet indifferently. By this ingenious arrangement the permanent magnet is quite unaffected by the currents received, or even by lightning, although a permanent alteration in the signal might be effected by a temporary atmospheric current—an error which could not arise where permanent currents are used to produce the permanent visible signal. The general arrangement is simple, and not likely to get out of order. The instrument can be adjusted to work with stronger or weaker currents by sliding a keeper along the permanent horseshoe magnet, leaving more or less of its magnetism to attract the pointer. Mr. Tyer's signals are extensively used on many lines of railway.

Siemens, Halske, & Co., M. (United Kingdom, 2,959), exhibit a magneto-electric railway alarum, used to announce the departure of each train from each station. These alarums are, in Germany, placed all along the line from one station to the next, at distances of from 1,000 to 1,200 yards apart. They consist of a large iron bell, 18 inches in diameter, struck by a heavy hammer driven by clockwork, which is started by the electric current. The signals can be heard at least 600 yards off. When a train starts from any station all the alarums between it and the next stations are sounded simultaneously. The currents are obtained from a magneto-induction system similar to that used in Messrs. Siemens' step-by-step instrument, but much more powerful; the coils and armature are placed between the poles of twenty-eight powerful horseshoe magnets, and are driven by a handle and belt.

The clockwork has several valuable peculiarities. The received current releases a delicate detent by an electro-magnet in the usual way. This detent does not directly start the clock, but allows a weight to fall, which knocks away a much heavier catch used to hold back the clockwork, the wheels of which then start, and continue to run until the hammer has struck a given number of blows. The clockwork then replaces the two detents and releasing weight in their former positions, and stops ready to receive another signal. About ten of these instruments are usually placed in circuit.

Lieutenant E. Vincenzi, Turin, H. M., Class V. (Italy, 1,006), exhibits a plan by which a railway train in motion may be communicated with at short intervals through a temporary contact

made between a spring on the break van and certain long bars placed every 1,000 yards along the railway, and connected with the two stations on either side by a line wire.

Cheyne & Moseley (United Kingdom, 2.281) exhibit a plan by which they propose to register the passage of each train at given points by marks on a strip of paper moved nearly uniformly along, as in the Morse recorder, and moreover dotted at fixed intervals by currents from a time-piece. They also propose to register every change in the position of danger signals, switches, &c., in the same manner.

11. *Lightning Dischargers.*

Among the adjuncts of a telegraph line we may here mention the lightning dischargers, of which a large variety is shown.

The British and Irish Magnetic Telegraph Company, M. (United Kingdom, 2,864), exhibit a rarefied air lightning discharger. This apparatus, invented and patented by Messrs. Bright in 1852, consists of a vessel exhausted to such an extent that any current of a tension* likely to prove injurious to the telegraphic instruments, or to a submarine cable, will find a ready passage from the line wire connection through the rarefied air to the earth connection, whereas the less intense currents used for working the telegraph will not pass across the rarefied air. The tension which will produce a discharge can be regulated by the extent of exhaustion in the vessel, and by the distance between the series of opposed points, in connection respectively with the earth and the line. The resistance to discharge through the exhausted air can be reduced far below that opposed by the thinnest practicable film of air between the points of the ordinary lightning dischargers, and the protection afforded is proportionately increased. No measurements of this resistance of the rarefied air appear, however, as yet to have been made. The communicating points are in this form perfectly protected against dust, &c., as the vessel is hermetically sealed. Abroad this is known as Bianchi's discharger, but the writer can find no mention of it prior to 1852.

Digney Brothers, M. (France, 1,414), and Bréguet, M. (France, 1,413), both exhibit two very common forms of lightning discharger. In one a couple of serrated plates are simply fixed on a board with the points of the teeth very close together; one plate is in the line circuit and the other connected with earth. The second form has two parallel plates facing each other, and each holding three pins with platinum points, which can be adjusted so as very nearly to touch the opposite plate; the plates are connected as in the first form. These dischargers are used in conjunction with a coil of fine wire, intended to be burnt by the passage of any very intense currents, as in the form exhibited by Mr. Walker in 1851. This invention of Mr. Walker's is now very generally adopted in all countries.

Siemens, Halske, & Co. (United Kingdom, 2,959) exhibit a lightning discharger which differs entirely from any other exhibited. It consists simply of two massive, flat, rough, metal plates thinly coated with varnish. One of these is in connection with the earth, and the other is in circuit with the line; one is simply laid on the other, but separated from it by four small thin slips of vulcanite, leaving a thin film of air between the two surfaces. When several lines enter the station, one large plate is in connection with the earth, and each line has its own small plate insulated from its neighbours, and resting on the large earth plate. The lightning is found to pass readily across the air and varnish at one or more of the many points of extremely close proximity which occur between the surfaces. The plates are frequently fused together by the discharge. Messrs. Siemens assert from long experience that this cheap and simple contrivance is preferable to any known arrangement of discharging points.

12. *Domestic Telegraphs.*

The review of the apparatus used in connection both with land and submarine telegraphic lines is now concluded, and, in order to complete the notice of signalling instruments, it remains only to mention the so-called domestic telegraphs, intended to supersede the ordinary bells in large public and private establishments. Several forms of domestic telegraph were exhibited in 1851, but they have as yet met with little success in this country.

P. D. Prud'homme, Paris, H. M. (France, 1,402), exhibits instruments which have been adopted with success in France, in large hotels and other buildings, where the usual system of bell-hanging would have been almost impracticable. There is no special novelty in M. Prud'homme's bell, which is the common "trembleur," sounded by the voltaic current from a couple of cells, so long as the circuit is completed, by pressing a button. Besides the bell, M. Prud'homme uses visible signals, consisting of letters or words on a disc of paper, moved in or out of sight by the deflections of a permanent magnet between the poles of two electro-magnets under the influence of reverse currents. The whole arrangement is simple, effective, and not likely to get out of order; a bell and visible signals are generally combined. The person answering the bell removes the signal back to its normal position by pressing a button, which sends a current back through the circuit in the opposite direction to that sent by the first caller.

The prices quoted by M. Prud'homme are extremely moderate, and were it not for the trouble of keeping the battery in order, electric bells might be introduced with advantage even into small establishments. The battery used is said, however, to work for many months without being touched.

The Universal Private Telegraph Company [Professor Wheatstone, Juror] (United Kingdom, 2,978) exhibit a domestic bell rung by a magneto-electric current, thus dispensing entirely with the battery. The depression of a handle transmits the current in the usual way, and releases the detent of an alarum.

IV. Philosophical Instruments, or Instruments used in Experimental Research.

1. *Apparatus for testing Submarine Cables, &c.*

Messrs. Siemens, Halske, & Co., London (United Kingdom, 2,959), and Messrs. Siemens & Halske, Berlin (Prussia, 1,413), both exhibit resistance coils arranged with a modification of Wheatstone's bridge or balance in a convenient form for testing the resistance of the conductor and insulator of submarine cables. Professor Wheatstone's bridge or balance is a combination of four conductors with a galvanometer and a battery, in which the galvanometer needle remains undeflected when the resistances of the four conductors form the four terms of a simple proportion. The arrangement is sometimes called Wheatstone's parallelogram, but the geometrical relations of the sides of a parallelogram are not those of the four conductors in the bridge or balance. Neither can it be strictly called a differential arrangement, except in the particular case in which the conductors form two pairs each composed of two equal resistances. On the whole, the name of electric balance is, perhaps, the most accurate.

The conductor, the resistance of which is to be tested, is so placed in the balance as to form the fourth term of the proportion, and its resistance is determined in terms of the three others, by varying one or more of them till the galvanometer remains undeflected, when the battery circuit is completed. This determination can be made in two distinct ways: first, by varying the ratio of the two first terms of the proportion; secondly, by varying the value of the third term. Both these plans are adopted in Messrs. Siemens' testing board. The conductors, which we have called the first and second terms, can be chosen at will, so that their resistances shall be equal, as one to ten, as one to one hundred, as ten to one, or one hundred to one. Moreover, the equality may be either equality between units, tens, or hundreds.

A set of resistance coils, varying from a single unit to ten thousand units, is so placed as to form the third term of the proportion. The test is made by first selecting the most suitable ratio between the first and second terms, and then altering the resistance of the third term until, when the battery is put in circuit, the galvanometer needle remains undeflected. The resistance of the conductor tested will then be either equal to that of the resistance coils of the third term, or it will be a decimal multiple or sub-multiple of that resistance. By this arrangement we can measure resistances one hundred times larger or smaller than could be compared with the set of resistance coils, if the only ratio between the first and second terms were that of equality. All the connections which require to be altered are altered by means of conical plugs fitted between the two brass terminals to be joined. The resistance coils are all permanently connected in series, and those not required in circuit are simply short-circuited by plugs. The insulation of the various parts is effected by vulcanite or ebonite, and the ebonite is mounted on a slate slab. From the above it will very clearly appear how the resistance of the conducting wire of a cable is measured. This wire is simply connected so as to form the fourth term as above; one end is connected with the board, and the other connected with the earth.

* By the word tension is here meant the difference of potential from that of the earth in the neighbourhood of the instruments.

The resistance of the insulator to conduction across itself, from the copper conductor inside to the water outside, is tested in exactly the same manner, and with the same connections, simply insulating the second end of the copper conducting wire of the cable, and if necessary changing the ratio between the two first terms. The insulating sheath is then simply in the position of a conductor of high resistance, one end of which, the inner surface of the sheath, is connected with the proper terminal of the board by the internal copper conducting wire (of comparatively insensible resistance), while its other end, the outside of the sheath, is immersed in water, and thus connected with earth, to which one pole of the battery and one end of the resistance coils (third term) are also connected. The insulation of a submarine cable depends on the relative resistance of the copper wire to conduction along itself from one station to another, and of the insulating sheath to conduction across itself from its inner to its outer surface. When these two resistances are known, a formula based on Ohm's law gives the proportion between the current received at the far end and that sent into the cable at the near or signalling end, showing the loss by the way. The resistance of the sheath, measured as above, also allows us to calculate directly by Ohm's law the current which would flow across the sheath with a given battery or rheomotor when the further end of the conductor is insulated. This current, as shown by the deflection of a galvanometer, is frequently called the loss from defective insulation, instead of the loss first mentioned. So long as the materials and dimensions of an insulated core are alike the loss, as last defined, will be simply proportional to the length of the cable, but will, of course, vary with the battery, the galvanometer, and the dimensions of the core tested, even when the material remains the same.

The *resistance* of the sheath is, on the contrary, independent of the battery and instruments employed, and very simple reductions taught by theory and practice permit us to deduce from the resistance observed the specific resistance of the insulating material—that is to say, the resistance of the unit length and section of that material. From this specific resistance we can conversely deduce the resistance of any sheath of any length and thickness, and the loss of current, whether defined in one or other of the two ways described above. The first insulation tests made on submarine cables were tests of the loss according to the second definition, but as no record was kept of the electro-motive force of the batteries, or the signification of the deflections of the galvanometers, these tests were nearly useless for the purpose of comparing one cable with another of different dimensions, but at best served to show whether, during the manufacture of the cable, the later portions were similar to those first made. At present, on the contrary, the *resistance* of the sheath is very generally measured, and by the specific resistance deduced from these measurements the excellence of the different materials at all different temperatures, and the relative perfection of the different cables manufactured by different makers at different times, are very accurately made known.

The measurement of the resistance of the sheath, or, as it may be called, the insulation resistance of a cable, has a second object, of perhaps still greater importance than the determination of the specific resistance of the material. A fault diminishes the resistance of the sheath, and conversely too low a resistance in any section of a cable indicates a fault, and is one of the chief means by which faults are detected. A fault here means the presence of any foreign substance of less resistance than the insulator in the sheath, joining the water outside and the conductor inside; thus a fault may be a hole or cut, which becomes filled with water, or a nail driven through the sheath to the copper, or simply dirt and other impurities in the insulating material.

Messrs. Siemens' arrangement is by no means the only one by which the resistance of the insulating sheath can be obtained. It may with proper precautions be obtained even from the loss (according to either definition) shown by the simple deflections of a tangent or sine galvanometer, or by differential galvanometers used in connection with resistance coils; but Messrs. Siemens' arrangement is simple, accurate, and effective when used for cores of some knots in length, for which alone it is intended.

(*To be continued.*)

MR. L. W. COURTENAY (late secretary of the Submarine Telegraph Company), after a short visit to England, returns to Constantinople with the next mail.

MR. COOKE'S PAMPHLET OR SKETCH OF 1836.

(*Continued from page 190.*)

IN reproducing in our columns this remarkable and highly-interesting sketch by Mr. Cooke, our object is to enable our readers to become acquainted with the early history of the electric telegraph, and of the labours of those to whom we are indebted for its practical realization. The author of the sketch described in a lucid and forcible language the great disadvantages of the system of telegraphing then in existence, and the manifest superiority for all purposes of communication of the plan he then proposed; yet what years of labour and solicitude rolled on ere his project found favour in the land which he and his illustrious coadjutor have since so immensely benefited! For a period of six or seven years the prospects of the electric telegraph were as gloomy as they are now brilliant. Viewed as a "philosophic toy," incapable of practical application, capitalists could not be found willing to embark in the undertaking. Government required no speedier means of communication than it already possessed in the old semaphore. Under such circumstances, we can easily conjecture the nature and extent of the difficulties to be surmounted in preparing the public mind to receive the project of an electric telegraph as one capable of practical application.

To proceed to the second subject of consideration proposed, viz., the providing a sure, speedy, and simple method of discovering the injured point in every case.

For this purpose short branches will be given off from the main wires, opposite to turnpikes on common roads, and station-houses* on railroads, into which buildings the extremities of the wires will be carried, and there secured in a lock-up box, or closet in the wall, of which the district-inspector will have the key. He will be furnished also with a simple electro-magnetic instrument about the size of a watch, containing a poised magnetic needle; upon connecting this instrument with the terminations of the branch wires, or with the main wires themselves, in the manner described in the note (the telegraphs being set as directed), it becomes immediately evident, by the deflection of the needle, on which side of the place of experiment the wires have been injured. As soon as the connection between two telegraphs is found to be broken, the inspector will proceed to discover, by successive experiments, the two consecutive turnpikes, or station-houses at which the effect on the needle is reversed. The injured point must evidently be somewhere in the interval between them; his next step will be to examine the intervening ground, to discover if there be any external marks to direct his further search; if none appear, he will divide the interrupted distance (which we will assume as 12 miles), and cause a hole to be sunk to the conducting trough, when the former experiment will be made upon the main wires. This halving of the intervening space, if repeated 12 times, will reduce the unexamined distance from 12 miles to 5 yards; whilst at each examination, the attention being directed nearer and nearer to the object of search, the probability of detecting external marks of violence will be increased. Thus, a very few hours from the discovery of the interruption will, under the most unfavourable circumstances, be sufficient to admit of the injury being detected and repaired.

Since such injuries could only be of very rare occurrence, the ready method thus afforded for detecting and repairing them, renders this very trivial liability unworthy of further consideration, and forbids its being viewed as any objection to the system.

Having obviated these apparent difficulties, we now proceed to notice some further advantages arising:—1st. From the nature of the instrument. —2ndly. From the extended application of telegraphing which it renders practicable.

Hitherto, *signals*, very slightly differing from each other, have been used in telegraphing, to represent either the letters of the alphabet, or numbers, corresponding with the signal key. In the electro-magnetic telegraph, the characters represented amount in all, as has been already stated, to 60, consisting of 22 letters, viz., A, B, C, D, E, F, G, H, J, K, L, M, N, O, P, R, S, T, U, W, X, Y; 10 English digits, viz., 1, 2, 3, 4, 5, 6, 7, 8, 9, 0, representing amount; 10 numbers, viz., I., II., III., IV., V., VI., VII., VIII., IX., O., in reference to the signal key; 14 symbols, viz., £, *s*, *d*, ÷ ?, ?, ,, ,, ,, ,, &c., &., (private symbol,) (government symbol,) and any other 4 symbols which may be found the most convenient for practical purposes, making 60 the total. NOTE.—It is found convenient to repeat the ? and ,. ÷ is a fractional sign, as 1 ÷ 2, or ½.

From 1,000 to 1,500 of these characters may be represented in an hour, so that with an extensive and well-selected compilation of sentences, questions may be put and answered, advice asked and given, and consultations of every kind carried on with no further loss of time, and

* By station-houses, may be understood all buildings connected with railroad lines, whether depôts, &c. near towns, or watch-houses where the main-roads are crossed, &c., &c. These generally occur at far shorter distances than 12 miles.

sometimes even with less, than would be requisite for making the same communications to the deaf and dumb, by talking on the fingers.

This advantage, which is great even at comparatively short distances, increases incalculably in importance when the places are very remote from each other.

The precision and certainty of the instrument are also deserving of observation. It is worked, in a very simple manner, by 16 keys or stops; each of these keys has the particular characters inscribed upon it, which the instrument can be made to represent by its action, and these characters are arranged in such positions as to indicate the direction in which the key must be moved for the representation of each. The greatest possible security is thus afforded that the attentive signaliser will, without fail, represent the character which he intends. Again, each character is about half-an-inch in diameter, so as to be perfectly distinct, and only one character being visible at a time, precludes any doubt in the clerk receiving information, whose sole business it becomes to copy down the several characters which are successively presented to his eye. Lastly, this one character being simultaneously represented on both instruments, the signaliser, if by accident he has laid his hand upon a wrong key, immediately observes his error, and will correct it by the following signal.

Inscrutable secresy is, obviously, of primary importance in the mass of telegraphic correspondence. This may, on a *primâ facie* view, appear a difficult object to attain, where the symbols are seen by a number of persons at the same time, without each corresponding party having a private signal-book, but the accompanying "Round-Robin" cypher* will at once show, from the innumerable changes of which it is capable, that a published signal-book may be employed on the most private occasions. These changes depend upon the fresh relative arrangement of the circle containing the letters, to that containing the figures, each time of the cypher being employed, however frequently it may be required during the day.

To illustrate this, suppose a card published with each signal key, with the letters and the numbers in the order of the annexed cypher. A London banker, in the habit of communicating on all extraordinary occasions with his country agents by telegraph, would furnish each of them with a private memorandum, of which he would keep a copy, to this effect (in adjusting the cypher).

Mr. J., Liverpool, No. in signal key, 3742, set 1st signal given to the day of the month.

Mr. P., Glasgow, No. 2314, set 2nd signal to the day of the month.

Mr. D., Edinburgh, No. 143, set letter H to the day of the month.

Mr. X., Dover, No. 415, set 7 to odd days of month, VII. to even, &c.

And so on with an endless variation, to which the most extensive correspondence could give no clue.†

Suppose the correspondence then to run thus:—

(Private symbol) L L 3742 }
(Private symbol) G 2314 } 782,641,39 ? £42 5 6½ Stolen.

The cypher transpositions would stand thus on the

1st January, { if to Mr. J. / if to Mr. P.
2nd January, { if to Mr. J. / if to Mr. P.

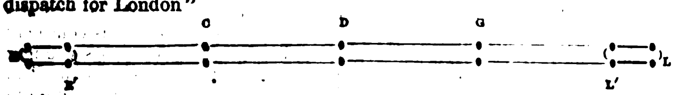
(Not filled up in the manuscript.)

At first this may appear difficult to transpose from the cypher card, but a very little practice gives great facility.

We proceed to consider the application of this system to the affairs of Government; of the commercial world; and of the private individual.

I. Application to the affairs of Government:—It will be generally acknowledged that an enterprise of this description, though carried into execution by a company, should always be under the control of the Government, that in case of dangerous riots, or popular excitement, the earliest intimation thereof should be conveyed to the ear of Government alone, and a check put to the circulation of unnecessary alarm. From the construction and character of the Electro-Magnetic Telegraph, great facility is given to the exercise of this control when requisite, without interfering with the enjoyment, by the public, of its fullest advantages on ordinary occasions. Let Government be supposed in possession of a distinct telegraph at either end of the line, when, by a single movement, the communication between the public telegraphs may be cut off.

Suppose E, L to be the public telegraphs at Edinburgh and London respectively; E′, L′, the Government telegraphs at those places; and C, D, G, telegraphs at intervening towns; when the signal, "Government dispatch for London"



is passed from E′ to L′, the connection between E′ and E, and between L′, and L will be immediately broken off, as the act of giving the signals, "Government dispatch for London," from the telegraph at E′, breaks off the communication between E′ and E; and, as the Government telegraphs will be differently arranged from those in public use, the communications would be unintelligible at the places C, D, G. On lines along which Goverment dispatches are most frequently transmitted, it might be desirable to lay down a distinct set of wires for that use, which would also diminish the risk of the communication being entirely interrupted by the accidental breaking of a wire. The wires of the public telegraph might then pass through the Government office, and be applied to the Government instrument at pleasure, when the usual arrangement of the signals could be restored. Commanding, by these means, immediate and sole intelligence of disturbances, &c., in different parts of the kingdom, the Government would be enabled, in case of disturbances, to transmit their orders to the local authorities, and, if necessary, send troops for their support, whilst all dangerous excitement of the public might be avoided.

II. Application to commercial affairs.—The advantages under this head are no less comprehensive and important. An immediate knowledge of the daily state of all the important markets, &c., would place the most distant cities of the kingdom on a footing in their mercantile transactions with the capital. The daily state of the money market, so eagerly expected on the Stock Exchange of London, would be looked for with equal anxiety at Liverpool, Glasgow, and Newcastle, at the same moment.

The security and confidence inspired by an actual knowledge of the existing state of things, would give a fresh spur to activity in all honourable mercantile transactions; while the unfounded reports now circulated by the swindler could no longer produce their effect. The capitalist of Glasgow might, without fear of an unfavourable change of price taking place during the interval, transmit to his agent in London, orders for the immediate sale or purchase of stock or shares; and the banker of the country, when pressed in time of panic, might be preserved from stopping payment, by assurance from the capital of extended credit. The offerer of false bills, on the other hand, would be in more dangerous circumstances, when his guilt might so soon be proved; and the culprit, escaping from justice, might be anticipated by intimation to the authorities on the coast.

For security against unfair dealing and neglect, copies of all communications given in for transmission at the office would be kept for the reference of subscribers, with date of the day and hour at which they were received, and the originals, countersigned as entered, would be returned; where unjustifiable delay or carelessness in forwarding the same was proved, the clerk would be subjected to punishment. This and other obvious regulations (not necessary to transcribe here), would ensure the same accuracy in the telegraph, which has established the character of the Post Office.

III. Application to the affairs of individuals.—The cases in which the convenience of individuals would be effected are innumerable; and perhaps there are few persons, however generally unconnected with the transactions of the busy world, who would not sometimes be spared either a lengthened epistolary correspondence or an expensive journey, by a few short communications through the telegraph. The comfort of friends and relations, far distant from each other, would often be materially involved, especially in cases of sickness; and it may not be too much entering into detail to specify that particular instance, where sickness appears hastening towards a fatal termination with such rapidity that a final meeting is without the range of ordinary means. Though the application of the telegraph to private affairs is less dazzling than that to Government and commerce, it is, perhaps, not less intrinsically valuable as equally tending towards the one and only justifiable object of all establishments—the aggregate of comfort and happiness to the nation. It may here be observed, that should it at any time be desirable for the Admiralty, in their communications with vessels lying off telegraph ports, to convey their despatches direct during the night, the apparatus in ordinary use, conveniently situated facing the sea, may, by a peculiar adaption of the hydro-oxide lime burner, arranged for this instrument, extend their correspondence many miles across the water. Even His Majesty's navy might be furnished with instruments of a simpler arrangement than that proposed for land service, to communicate signals during the night, the action of which would not be interrupted by the motion of the vessel during bad weather. For short distances of a few miles, a powerful argand lamp would answer this purpose effectually. We will specify one further instance nearly allied to many others, in which this telegraph might be advantageously employed. It is observed by Dr. Lardner, in his work on the steam engine, at the 219th page, when speaking of the inconvenience to which locomotive engines are exposed in surmounting inclined planes on railways, that "a subsidiary, or assistant locomotive engine, may be kept in constant readiness at the foot of each incline, for the purpose of aiding the different trains as they arrive, in ascending. The objection to this method is the cost of keeping such an engine, with its boiler continually prepared, and its steam up. It would be necessary to keep its fire continually lighted, whether employed or not; otherwise, when the train would arrive at the foot of the incline, it should wait until the subsidiary engine was prepared for work." This plan is adopted.

How soon would the proprietors of railroads be repaid for laying down wires along a few miles of road leading to such ascents, by which timely intimation of the approaching train might be forwarded to the engine-man, with notice to prepare? and how effectually would this remedy the costly inconvenience described?

Lastly, consider the sources whence a revenue, adequate to defray the

* This cypher has been lost.

† Short expressions, such as "I," "and," "to," "by," "of," "you," should always be avoided in cypher correspondence, as affording an easy clue to a certain number of letters.

original outlay and current expenditure of such an enterprise, may be derived. If a company undertake the execution, under the control of Government, a proportionate remuneration for the forwarding of official dispatches may be expected from that quarter. In each town where a telegraph was established, various classes of subscribers would be admitted to the privilege of receiving and forwarding their private correspondence, and of being made immediately acquainted with the general news of the day. These might consist, 1st.—Of perpetual subscribers or shareholders, admitted to the subscribers' room, where all general, political, and mercantile news would be published as soon as received. 2ndly.—Annual subscribers. 3rdly.—Temporary subscribers for some special purpose. 4thly.—The occasional subscriber for a single dispatch. Each of the three former, in addition to his subscription, would pay, on employing the telegraph, according to a fixed scale, proportioned to the length of the dispatch and the class to which he belonged.

If any interference, which an extensive establishment of this telegraph might create with the Post Office, be viewed as an encroachment upon the revenues of Government, it will be remembered that communications by telegraph may be taxed as well as those by post; and as this interference would be almost insensible in any case, Government would gain, not lose, by the event.

The writer does not propose to go into a lengthened statement of the minor details of his plan on the present occasion, but to give only such a sketch as will enable the reader to form a general idea of it as a whole.

It may, however, be desirable to explain the nature of the signal-key which he purposes employing, although perhaps offering nothing new in its design.

The numbers in reference to the signal-book, it has already been explained, will be formed on the telegraph, in the Roman character (or else broad printed type) for the purpose of distinction.

The signal-book or key might advantageously have two sets of numbers; the first, for general use, in reference only to daily reports, sentences, words, &c.; the second, which would be indicated by the signal (private) preceding them, might be appropriated to the names and directions of subscribers. Hence, a telegraphic notice commencing with (private), followed by a number, would intimate that the symbols following, after being taken down and copied into the day-book, should be forwarded in the usual way to the person whose address that number signified; when followed by the signal (express), an additional charge would be made for despatching it on the instant. An abbreviated mode of spelling (a kind of short-hand) would generally prove more expeditious for the public office than the employing numbers to express single words. The towns would be most easily recognised by their initial letters; and when on the same line two telegraphic towns commencing with the same letter occurred, one might be designated by both the first and last letter, as L. for London; L. L. for Liverpool; N. for Newcastle; N. M. for Nottingham, &c. A clearly-printed list of these abbreviations and their meaning, together with the numbers of daily reports, might be fixed before the clerk attending the telegraph, for ready reference. When, if at Leeds, on the York and Liverpool line, he saw, after the alarum had been sounded and been answered, the letters L L. follow on his telegraph, he would leave the further attendance on the signals to his compeer at Liverpool.

The duties of a clerk of the telegraph would be extremely simple, requiring only accuracy and attention in noting down and transmitting notices with a certain degree of expertness, easily attained in working the instrument. These qualifications are frequently possessed, in a remarkable degree, by a very deserving class of persons, to whom our state of society has hitherto assigned no congenial occupation. The deaf and dumb might, in the telegraphic department, find employment peculiarly suited to their education and powers. Accustomed from their infancy to abbreviate as far as possible, by signs, their symbolic language, they would quickly attain a degree of conciseness in spelling, which, in addition to the omission of the smaller words, would enable them to transmit, with astonishing rapidity, a lengthened despatch; whilst a habit of attention, enforced by their infirmities, would be favourable to the accurate performance of their duties.

The idea of uniting a great political and mercantile enterprise with a charitable object may excite a smile, but cannot diminish the value of the undertaking in the eyes of those whose support the writer is most anxious to ensure. It may be observed, that a method as effectual as the alarum for those who can hear, may be employed in connection with this instrument, to awaken the deaf from the soundest sleep.

A general outline has now been given of a system by which the knowledge of passing events may be propagated instantaneously to distant parts, together with a view of some leading advantages which may reasonably be expected to result therefrom.

To what the introduction of this system may eventually lead, the writer does not venture to predict, but concludes these observations with the following quotation from Dr. Lardner's work already mentioned, a passage which may be applied to the action of the Electro-Magnetic Telegraph as forcibly as to that of the steam-engine, and, indeed, corresponds most happily with the united action of both. It runs thus:—"The moral and political consequences of so great a change in the powers of transition of persons and intelligence, from place to place, are not easily calculated. The two advantages of increased cheapness and speed, besides extending the amount of existing traffic, call into existence new objects of commercial intercourse. The concentration of mind and exertion, which a great metropolis always exhibits, will be extended, in a considerable degree, to the whole realm. The same effect will be produced as if all distances were lessened in proportion in which the speed and cheapness of transit are increased. Towns at present removed some stages from the metropolis, will become its suburbs; others, now a day's journey, will be removed to its immediate vicinity; and business will be carried on with as much ease, between them and the metropolis, as it is now between distant parts of the metropolis itself."

(To be continued.)

THE ATLANTIC TELEGRAPH.—OUR RELATIONS WITH AMERICA.

On Friday evening last the friends of the great enterprise for connecting the Old World with the New, by the agency of the Electric Telegraph, dined together, on the invitation of Mr. Cyrus Field, at the Palace Hotel, Pimlico. There were present:—His Excellency the American Minister, Lord John Hay, Hon. R. Grimston, Mr. Bright, M.P., Mr. S. Gurney, M.P., Mr. G. P. Bidder, Captain Osborn, R.N., &c.

The Chairman (Mr. Cyrus Field) having proposed the health of his Excellency the American Minister,

Mr. Adams replied, and, in the course of his observations, said he felt most thankful for the kind way in which the company had received the allusion made by the chairman to the humble efforts which he had been making during the last three years, to preserve harmony between two nations of the same race, the same language, and the same religion, at a time when there was great danger that they would differ. In the little observation which he had been able to make during the period he had had the honour to hold the position which he at present occupied, there was one thing which struck him more than anything else had, and that was the existence of prejudices on both sides of the Atlantic, which only required for their removal a little more familiarity between the two peoples. (Cheers.) He had seen statements made in the public prints of this country with respect to the acts of his country, which he was sure would never have been made had those who gave expression to them personally known the truth with respect to them. (Hear, hear.) Likewise, on the other side of the Atlantic, there were newspapers which indulged in certain statements with respect to Great Britain, which he was sure they would have never uttered had they truly known Great Britain, and the true feelings of the British people. It was in the cause of civilization most important that the harmony between the two nations should be maintained unimpaired, and he knew no better means of doing so than the establishment of the electric telegraph between the two countries—a project, to the execution of which Mr. Field had devoted his talents and his life, and which, should it be effected, would rank as the most memorable and the most glorious event in the history of the world, and secure an immortality for the reputation of their worthy host. (Cheers.)

The Chairman, in proposing the health of the hon. gentleman the member for Birmingham, took occasion to say that he very much wished his hon. friend would visit the United States, where he promised him he would be received with an ovation such as no man living ever received. The only danger was that all the male children born in the course of the year in which he might so honour them would be named after him, and, instead of being Browns and Joneses, they would be all John Brights.

The toast having been enthusiastically honoured,

Mr. Bright said:—Gentlemen, I might very easily rob Mr. Field of the originality of the statement he has made of what might happen were I to pay a visit to the United States. I have in the course of time received many letters from gentlemen in his country, and one of them did say there were several penalties I should have to endure as the consequences of my visit to America, and one of them was, he thought, that nearly all the children there would have to be called after me. (Hear, hear. and laughter.) If this and a great many other dreadful things which he thought would follow my visit be true, I am, I think, very prudent in staying in this country. (Hear, hear.) I have never been in America, but for thirty years, which is a long time to look back to, I have had a strong wish to go there; but most of us Englishmen find so much to do in the conduct and management of our regular business, that a six months' absence is not a thing easy to accomplish. Englishmen are, I think, I will not say more attached, but certainly much more tied to their homes than Americans are. However, when Mr. Field is able to tell us that the war is over—(hear, hear)—that the Union is restored—(hear, hear)—that there are none but free men on his continent—(hear, hear, and cheers)—if I could say I might be a few years younger than I am likely to be when that happens, I might perhaps be induced to promise to pay a visit to America. I do not know how many of those in this room are Englishmen, nor how many are Americans, nor is it at all necessary to discriminate between them, but it is, I think, worthy of notice that you cannot tell one from the other. (Hear, hear.) That is not an unreasonable thing, seeing that our ancestors were your ancestors. (Hear, hear.) But it is a very provoking thing, if anything be so, that there should be people who would make us foreigners and strangers to each other. (Loud cheers.) I am convinced that it is possible to go through the United States, and select a number of gentlemen, English and Americans, equal

to the fifty or sixty gentlemen who are now present, and that if you put them together, one half with the other, you would find them just as friendly disposed towards each other as we are, and just as able to enjoy the good things provided for them. (Cheers.) There would not be among them the slightest disposition to quarrel one with another. (Hear, hear.) On the contrary, they would begin to think that all that has been said to create a hostile feeling between them is false, and then the lies and frightful calumnies which a great newspaper in this country—(hear, hear)—and another great newspaper in New York—(hear, hear)—treat both hemispheres to would no longer be regarded. (Cheers.) There are some persons in England very jealous of America. They think it is too big to govern itself—to be under one Government. They—the subjects of a State which governs an empire of 160 millions of people of a different race, some thousand miles away—they, I say, have a profound conviction that thirty millions of people, of the same race, language, and religion, are really too large a population to be governed by themselves and to constitute one State. (Hear, hear, and cheers.) This national jealousy is very stupid, to say the least of it. (Loud cheers.) When the grandfather of the distinguished guest beside me was here in the same capacity which he now occupies, he was here in times of great animosity, in times of great displacement of old feelings, and in times of great national irritation—(hear, hear)—for the American colonies had just then emancipated themselves. After the war of 1812 his father came here in the same capacity, and he curiously enough also came in for a portion of that kind of national irritation, the result of the war not having been very flattering either to the policy or the forces of England; and now our friend is here at a time when, although we are not at war, yet when war is producing very unfortunate results here, especially in regard to one very important branch of commerce, and is stirring up memories which had better been buried for ever. (Loud cheers.) From all this there comes—there comes from men, some partly ignorant, some suspicious, men of contracted intellect, totally ignorant of what makes the great and true glory of nations—a jealousy of the United States. (Hear, hear.) In ancient times it was considered the glory of nations to plant powerful colonies, and they did not glory the less in them because they became independent. (Cheers.) The United States have ceased to be our colonial possessions, and are now truly an independent nation, but still they are our colonies. (Cheers.) What, then, can be more contemptible, and flying in the face of all that is great and glorious, and all we are taught in history to value, than that we should feel jealous of the great nation on the other side of the Atlantic, planted there by ourselves? (Cheers.) We have achieved whatever glory we are entitled to for having been able to carry everything good in this country to a higher point of excellence than any other country of which we are told in history ever did. (Hear, hear.) We have lately heard a great deal about the advantages of a universal language, and if I am disposed to talk often I am not the less disposed to listen and be taught, and I know nothing more irritating and irremediable than the story we are told of what took place in the tower of Babel, by which men are supposed to speak in different tongues not mutually understood; but in the United States there are thirty millions of people of the same race as ourselves, professing the same religion and speaking the same language, so that when peace is restored, the Government re-established, schools and classes enough open for the general and religious instruction of the people, and freedom universally established, there will be a vast field opened for the development of commerce, civilization, and Christianity, and the population will every ten years grow to a degree that even in the lifetime of our children the English language will be spoken by 100 millions of free people. (Hear, and cheers.) What a magnificent contemplation that is. (Renewed cheers.) If I chance to go further, to the Australian colonies, which under the blessing of free institutions are becoming great and populous, I find that there the English language is spoken as it is spoken in the United States, and, again, if I come to our vast dependencies in India, inhabited by 150 millions of people, among whom the English language is daily and yearly extending its influence, so that by means of the care of schools and a good educational system we shall have the educated people of Hindostan twenty or thirty years hence, should the connection continue so long, speaking the English language. (Cheers.) Finally, I come to South Africa, and there the English language is making its way also among various different nations, so that we see that this language of ours, in which some of the greatest and most eminent men who ever lived have written and spoken, is universally extending itself by the help of commerce and civilization, until it promises to belt the world. (Cheers.) I want, then, to know why there should be any persons inclined to keep up cavil, to excite and stimulate jealous passions and a hostile mind between two nations speaking this language. (Cheers.) I cannot conceive any man more an enemy, not only to his country and the cause of freedom, but also to humanity itself, than he who lends himself to create and foster jealousy and animosity between the United States and this more ancient English nation. (Cheers.) I thoroughly agree with what Mr. Adams has said with regard to the political importance of that great undertaking in the cause of which we are this evening assembled; and just before I came here I was speaking to a gentleman, a member of her Majesty's Government—one of the present Cabinet—and I told him, as I was coming out of the House, that I was going to dine with some friends of the Atlantic telegraph. His countenance at once brightened up, and he said to me, "I look upon that as the most glorious thing that man ever attempted; there is nothing which so lays hold of my sympathies." (Cheers.) When he said that he spoke only the feelings of every intelligent and moral man in the whole world. (Loud cheers.) When the news reached us that the last cable was laid, did it not make a revolution and a shock? Did not every man feel that a new world and a new time were opened to him? It was, I recollect, just at the time when some great work was being inaugurated at Cherbourg under the auspices of the French Emperor, but it sank into insignificance compared with such glorious news, and everbody felt, as everybody must have felt 400 years ago, when the simple, adventurous sailor of Genoa had opened a new world to the knowledge of mankind. But he only discovered to Europe what I may be permitted to call an unoccupied wilderness; but this project is one to unite 30 millions of people to the 250 millions who inhabit this continent of Europe, and passing from the days of Columbus I know of no event in history comparable in grandeur and sublimity (if we look at its results) with that magnificent enterprise to which Mr. Field has devoted his talents and his life. (Cheers.) I thank you for your kindness in listening to me so far, and I hope that some short time after this great event shall be accomplished we may have the satisfaction of seeing Mr. Field amongst us again to congratulate him on the result to which we look forward with so strong, so intense an interest. (Loud cheers.) The hon. gentleman resumed his seat.

The Hon. Mr. Evarts, of Boston, Massachusetts, also spoke to the same effect upon the political importance of the telegraph. Its commercial advantages and prospects were the subjects of able speeches from the Hon. R. Grimston, Mr. Brassey, and other gentlemen.

LAW INTELLIGENCE.

Newall v. Glass.—This was an action for the infringement of a patent for an apparatus used in laying down submarine electric cables for telegraphic purposes, and after a trial at Westminster, before the Lord Chief Baron, which lasted several days, the jury found a verdict substantially for the plaintiff. Mr. M. Chambers, Q.C., on the part of the defendant, now moved for a new trial, on the ground that the verdict was against the evidence, and also on several other grounds. At the trial the learned judge directed a verdict to be entered for the defendant on some of the issues. The patent was for a mode of stowing on board a vessel an electric cable so as to enable it to be paid out without kinking or getting into knots, and the apparatus consisted simply of a cone composed of spars, round which the cable was coiled. The Lord Chief Baron said it was a patent for the use in a particular way of things which were to be found on board of every vessel. The patentee did not propose to make the cone or the coil, but asked for a royalty or tax from all persons who adopted his particular arrangement. He (the Lord Chief Baron) owned that in his opinion a man could not have by law, a patent for a thing he did not make. The plaintiff really said, "You shall not use your own materials in a particular way for letting out a cable, unless you pay me a royalty;" but that was a new mode of taxing the British public, to which they would be very great enemies. The Court granted a rule *nisi*.

CORRESPONDENCE.

BONELLI'S TELEGRAPH COMPANY.

To the Editor of the Telegraphic Journal.

Sir,—I should be obliged by your finding space in your next issue for the enclosed letter.—I remain, yours truly, Henry Cook.

[Copy.]

Sir,—With reference to the reprint of my Report to the Jurors on Bonelli's instrument you ask me whether my views of the value of that invention have remained unchanged since 1862.

I have now the pleasure in saying that my opinion of the arrangements is now much more favourable. The practical test I went through necessarily has been successfully made, and five wires have replaced the eleven used in the working model exhibited—a substitution which alone doubles the value of the invention. I have also by a calculation ascertained that the required speed can be maintained on land lines of much greater length than I had anticipated; and this calculation is confirmed by experiments which you inform me have been made by the Chevalier Bonelli. You are mistaken in supposing that even in 1862 I thought unfavourably of the invention. It was necessary, in justice to other exhibitors, that I should point out what I considered to be weak or doubtful points; but if you turn to page 47 of the Report, you will find that I mention one main advantage which the plan has over all other automatic arrangements, viz., that it alone dispenses with what I call the second transcription of the message.

To this I will now add, but although other automatic instruments will undoubtedly transmit a larger number of words per minute (of course, in conventional signs) with an equal number of wires, I think Bonelli's system peculiarly trustworthy, and free from liability of error.

6, Duke-street, Adelphi, Yours very truly, Fleeming Jenkin.
April 13, 1864.

To the Editor of the Telegraphic Journal.

Sir,—It is greatly to be hoped that your correspondent "G. R." may be more accurate in his appreciation of the instruments he intends to describe, than he is in the case of those which he has undertaken to abuse. As the alternative to ignorance would be a very painful one, I assume that "G. R." is ignorant, and beg to inform him that Bonelli's instrument requires five, and not nine, wires. That with these five wires it can get through a vastly greater amount of work than any other instrument with an equal number. And, lastly, that the cost of a five wire line is nearly double, and not as "G. R." attests, five times that of a single line.

To expose the absurdity of "G. R's" assumption, that the chances against uninterrupted communication on a complex line, are "not merely as the number of wires, *but* as their combinations," would be to insult the intelligence of your readers.—I am, sir, yours obediently, Henry Cook.

SPEED OF TRANSMISSION.

To the Editor of the Telegraphic Journal.

Sir,—I have read with considerable pleasure the interesting communications which have appeared in your columns on the speed of transmission attained on various instruments. We have had a vast amount of incomprehensible twaddle enforced upon our attention for some time with respect to the number of words which can be transmitted along an insulated wire in a given time. The writers are evidently ignorant of the practical operations of telegraphy, and the nature and construction of the various instruments employed. The laws of transmission are well known, but the action of the current on various instruments must be taken into consideration; for instance, the current does not act in the same manner upon the Hughes and the Morse instruments, and several others which I might mention. I am glad to find that the Bonelli and the Hughes instruments are to have a competing trial. Would it not greatly benefit telegraphy to have every known instrument put on its trial at the same time? J. L. Davis.

BALATA.

To the Editor of the Telegraphic Journal.

Sir,—The advent of a new material well adapted for insulating purposes is a matter of considerable importance to the telegraphic world. The enormous expense of gutta percha and india rubber almost acts as a prohibition to the extension of submarine telegraphy. The new gum, it is said, can be procured in inexhaustible quantities, and at about one-fourth the price of gutta percha and india rubber. At a recent meeting of the French Academy of Science, M. Serres gave a very interesting account of the gum. M. Serres affirms that the material is superior for many purposes to gutta percha, and more especially as an insulating material for telegraphic wires. Sir William Holmes has forwarded samples of the gum to the Society of Arts from Demerara, and states that it can be supplied to any amount. I believe that extensive experiments are being carried on at the present time, to ascertain the properties of the newly-discovered gum, with a view to its extensive application for insulating and other purposes. Having been favoured with some specimens of the material in the state in which it is imported into this country, I have subjected it to a few but stringent electrical tests, and the results are very favourable. The gum is remarkably free from foreign matter, and much resembles in texture well-cleansed gutta percha. Its insulating power is higher than that of virgin or unmasticated rubber, but about 15 per cent. less than that of masticated rubber. In comparison with gutta percha, I find that it insulates nearly 25 per cent. better, and that its inductive capacity is considerably below that of gutta percha. From its appearance, its firmness, and pliability, it appears to me to be exceedingly well suited for insulating telegraphic wires. However, I hope that I shall be able in a short time to furnish you with a fuller account of the investigations upon which I am engaged than I am at present prepared to do. I have myself perfect confidence in both gutta percha and india rubber as insulators for submarine lines; but the introduction of a material possessing all the requisite qualities at one-fourth the price, would be hailed by every one interested in the development of the science of submarine telegraphy.

20th April. I am, yours, &c., Experimentalist.

TELEGRAPHIC NEWS.

Bonelli's Telegraph Company.—We understand that His Royal Highness the Prince of Wales has expressed a desire to witness the operations of Signor Bonelli's ingenious apparatus, and that the instruments are to be exhibited to His Royal Highness at Marlborough House upon His Royal Highness' return to town from Sandringham Hall.

Atlantic Telegraph.—Mr. Cyrus W. Field, after a lengthened visit to England, takes his departure for New York with the next mail. The success which has attended his labours in the advancement of the great undertaking with which his name has so long been identified, is by this time familiar to all our readers; and we sincerely trust that Mr. Field, long before the expiration of the year 1865, will be able to receive the congratulations of his numerous friends on this side of the Atlantic through the submarine cable now in course of manufacture.

The Persian Gulf Telegraph.—Advices have been received from Sir Charles Bright announcing the entire completion of the Persian Gulf cable on the 27th of March. The line was working excellently through its entire whole length. The land-line between the head of the gulf and Bagdad is not yet completed. The above intelligence appeared exclusively in this journal last week.

Electric Telegraphs in New Zealand.—£150,000 has been set apart by the General Assembly from the £3,000,000 loan lately sanctioned for the purposes of telegraphic communication; and £75,000 has been allotted for telegraph works carried out within a period extending to March, 1865. The first portion of the main trunk line is now nearly completed, and messages will shortly be transmitted along that section.

The Indo-European Telegraph.—From the *Bombay Gazette* of the 29th ultimo we learn that "The Persian Gulf telegraph expedition continues to be singularly successful. The work of submerging the second great section of the cable (from Cape Mussendom across the Gulf to Bushire) was completed on the 22nd inst., and the Bombay Government has now the means of direct telegraphic communication with the British residents at Bushire, a matter of no small political importance at this moment. The laying out of the third and last section of the cable (from Bushire to Bussora) has not yet been commenced; but it is reasonable to anticipate that by the time this mail reaches England the whole line will have been finished and placed in proper working order. The sole cause of anxiety is the hostility of the Arab tribes, who have become very troublesome near Mussendom as well as at the head of the Gulf. Her Majesty's ship Vigilant, Commander Hobson, has gone up the Gulf to keep watch over the telegraph stations on the coast."

The Spezzia and Corsica Cable.—The submarine telegraph cable in the Mediterranean between Spezzia and Corsica has just stopped working. A vessel with telegraphic engineers and workmen on board is on the point of starting for the purpose of repairing it. This cable was submerged in 1853, and is the oldest as well as the first deep-sea line of great length laid down. It contains six conductors. At the close of 1863 only four of these wires ceased to work for the first time, and the two others have only stopped working during the last few days. We cannot help remarking the coincidence between the cessation of this cable and the death of him who laid it in 1853—we speak of the late J. W. Brett, the founder, it may be said, of submarine electric telegraphs. As for the cable, it appears easy to repair it. It will still long preserve—at least let it be hoped so—the reputation of being the best and oldest of all the great submarine cables, of which the average duration has not exceeded fifteen months.

Bonelli Telegraph.—The visitors to the Royal Institution, Albemarle-street, had an opportunity afforded them on Friday se'nnight of witnessing the working of the Bonelli telegraph. A large and fashionable company having assembled to hear a lecture by Professor Blackie on gun-cotton, proceeded at its close to the reading-room, where a Bonelli telegraph apparatus was placed at either end of the room, and by means of which messages were transmitted and received with the rapidity of thought, and printed at length in Roman characters. Mr. Cook, the managing director of the Bonelli Telegraph Company, and who has been indefatigable in his endeavours to promote the extension of the system, attended on the occasion, and explained the working of the apparatus to a much interested audience, and supplied them with slips with the messages received. Mr. Cook stated that one of the Bonelli instruments would do the work of thirty-two Morse and forty-eight needle instruments, and that an experiment had been made between Manchester and Liverpool for the purpose of testing the speed with which messages could be transmitted, and that 897 messages of twenty words each had been forwarded in forty minutes and nine seconds. Mr. Cook also stated that the Chevallier Bonelli had obtained permission to establish a telegraph mail between Milan, Turin, Genoa, Florence, and Trieste.

The following communication appeared in the daily journals of the 20th ult.:—"To the Editor. Sir,—A challenge having been given by the United Kingdom, and accepted by the Bonelli Telegraph Company, for a competitive trial of the relative merits of the systems of Hughes and Bonelli, it has been thought advisable, as a proof of the *bona-fides* of the pretensions put forth by Bonelli's Company, not to close the lists as had been intended, on the 30th instant, but to defer it to the 7th of May. The trial, so far as the Bonelli Company can influence the matter, shall be immediate, and certainly will not be deferred beyond the 30th instant. The refusal or neglect of either company to submit to the proposed test by this date must be considered as an acknowledgment of defeat. I am, sir, your obedient servant, J. Gutteres, Sec. (pro tem.)"

The Application of Electric Power to Railway Breaks.—It is some time since we took occasion to notice a pamphlet, in which was embodied an account of a most ingenious application of the voltaic battery to the mechanical arrangement necessary for arresting the progress of a train of railway carriages. The invention was that of M. Achard, a French engineer of considerable eminence, and had received at the time of our previous notice the approval of M. Duchoiz, the inspector of the railways between Paris and the Mediterranean. The apparatus has been at work for some months on the Paris and Strasbourg line, and we hear that its practical usefulness has been so well proved that fresh carriages are being fitted up with the machinery, which may be thus described (allowing for always recurring difficulty of making descriptions of machinery intelligible without

the help of models) to convey a tolerably clear idea. The break is worked by electricity in the following way :—The voltaic battery is placed in the break-van, and by means of insulated wires the electricity is conveyed from one end of the train to the other, communicating with the double magnetic coil placed near the axle of the break-van. At the poles of these two coils are two iron sliding-plates, bolted together at the top and at the bottom, holding a click, which, when the breaks are being put on, drops down and works into a ratchet-wheel until the breaks bring the wheels of the train to a skid. When the electric current runs through the train the coils hold the sliding-plates and click up, and the apparatus remains out of gear; but as soon as the current is intercepted a spring brings them down to act upon the ratchet. An eccentric wheel fixed on the axle of the van works the click up and down, and at each revolution moves the ratchet-wheel a certain distance. To the shaft of this wheel is fixed a double clutch box, and between a loose drum with a clutch at each end, so that it is no sooner released from one side than it falls into the clutch-box on the other. To this drum is attached a chain acting upon the lever of the ordinary blocks, and pressing them lightly against the tires of the wheels. As the rachet-wheel turns the drum turns with it, and lightens the chain until the train stops, and to release the break the drum is shifted by means of a lever from one clutch-box to the other, the play between the two being sufficient for that purpose. As soon as the break is released and the current of electricity reversed, the first turn of the wheel raises the working click above the ratchet-wheel, and the coils hold it there by means of the sliding-plates, so that it does not come into operation until the electricity is again disconnected. One great advantage of this is, that in the event of the couplings of a train breaking in going up an incline, or part of a train running off the metals going down an incline, or in case of fire, the breaks would act automatically and stop the train. We have had the satisfaction of examining a working model of the invention; and our own opinion is very favourable to the efficiency of the principle and of the power employed; and we understand that the locomotive superintendent of two of our London lines have received instructions to go to Paris in order to see the break in actual operation. Of course great interest attaches to the report of these gentlemen. In the meantime we may say that the model which we have inspected was of remarkably ingenious construction, and did not suggest to our mind the possibility of any mechanical obstacle occurring to the efficient carrying out of the invention.

MISCELLANEA.

Coating Iron with Aluminium.—Mr. William Clark has invented a peculiar process for covering the surface of iron with a layer of the latter metal. The surface of the iron is first cleansed; a mixture is then made of porcelain-clay, feldspar, and white-lead, properly ground and incorporated; then about ten parts of this combination are added to about five pounds of calcined and powdered alum-clay. This last mixture having been made into a thin paste, and poured over the surface of the metal, the latter is dried and placed in a reverbratory furnace until it presents a glazed appearance. When the iron is removed it will be found to have received a tough adhesive, and elastic coating, which is so closely attached to the metal that, when this is bent, even at right angles, no symptoms of cracking appear. This coating is also unacted on by acids and alkalis. It is supposed that during the baking process the aluminium is separated from its oxide, and forms a thin metallic stratum, intermediate between the iron and the glazed surface.

Novel Electric Fuse for Blasting Purposes.—This, which is a French invention, differs from all those previously employed, and appears to be highly spoken off. It admits of being rapidly manufactured, whilst the chances of fracture are reduced to the smallest number. It consists of an insulated wire, to which the usual fuse-tube is attached, and has a second wire, uninsulated, coiled round it, so that its extremity is about a centimetre from that of the first. Finally, there is a bag attached to its extremity, containing the explosive compound. When an induced current is passed through the wires, the spark traverses the powder contained in the pouch: it melts the thin thread employed to complete the circuit, and passes through both wires. By adopting this process a great number of blasts can be exploded simultaneously, as there may be branch wires from the main stem to various other localities.

The Real Nature of the "Electric Fly."—The piece of apparatus which bears this name has had its history well worked out by Mr. Charles Tomlinson, who has compiled for the benefit of natural philosophers, an account of the various theories held regarding the character of this instrument. Mr. Tomlinson has been led, from his numerous experiments, to conclude that the theory requires a different expression for an aerial as compared with a liquid di-electric. It seems to have a different action in airs of different densities, and also according as it is wholly or partially enclosed. Its action, when the points are covered, is also distinct, and is equally peculiar in the presence of flame. Hence it may be said, that "there is no one expression that fairly represents the electric fly. It modifies its behaviour according to circumstances; and, like a good subject, has no law of its own, but conforms to the laws of the community of which it is a member."—*Philosophical Magazine.*

The South of England Literary and Philosophical Society.—This society has been formed to meet the generally expressed want of an association which should serve to bring together occasionally and to promote the co-operation of those who in the town of Southampton and the surrounding neighbourhood are occupied in the pursuit, or interested in the progress of literature and science. Societies of a similar nature exist in all the large towns of the midland and northern counties, and there appears no reason why the important and populous area of which Southampton is the centre, should be unrepresented in the great body of educational institutions which these societies form. Not only is the district which the operations of such a society would embrace, rich both in natural history productions and in objects of antiquarian interest, but Southampton itself in its scientific institutions, such as the Royal Military Hospital and Army Medical School, the Ordnance Map Office, and the Hartley Institution, possesses the materials for a scientific organization at least equal to that of any town of the same size in the kingdom. The objects which the society has in view are the cultivation of literature and science, including archæology, by periodical meetings for the reading of papers, exhibition of objects of interest, and discussions thereon; and by excursions, *conversazioni*, and other similar means. It is pleasing to us to note that Mr. W. H. Preece, C.E., Superintendent of Telegraphs in the South Western districts of England, has contributed largely to the success of this society by his literary labours and scientific researches.

PRICES CURRENT OF INSULATING MATERIAL.

Gutta Percha, as imported.

Genuine, fine and good	2/2 to 2/6 per lb.
Good re-boiled	1/6 to 1/8 „

India Rubber.

TO CORRESPONDENTS.

L. D.—Your communication will appear next week.

Amicus.—Mr. R. S. Culley's "Hand-book of Telegraphy" can be obtained of Messrs. Longman, Green, & Co., Paternoster-row, London.

A Subscriber is thanked for his suggestions.

Communications intended for publication must be authenticated by the names and addresses of the writers; not neccessarily for insertion.

Letters relating to Advertisements are to be addressed to the Publishers. All other letters and communications to be addressed to the Editor of the *Telegraphic Journal*, 5, Suffolk-lane, Cannon-street, London, E.C.

Advertisements must be delivered to ensure insertion before Seven o'Clock on Thursday evening in each week. The charges for Advertisements are—

ON THE APPLICATION OF ELECTRICITY TO DOMESTIC PURPOSES.

By WILLIAM HENRY PREECE, Assoc. Inst. C.E.

(*Continued from page* 195.)

5. *The Indicating Tablets.*—Now the peculiarity of the French system is this: they do not use one bell for every room, as we do, distinguished for each particular chamber by its sound or note, but they allow one bell to answer for any number of rooms, and the particular room that rings is indicated by a number displayed upon a tablet. An hotel is ranged in floors. There is one bell to each floor, and an indicating tablet with the number of every room upon that particular floor designated upon it. A floor may be divided into galleries, and each gallery have its separating indicating tablet. The particular range of rooms under the charge of one set of servants has its particular bell and tablet, which are fixed where the bell is easily heard and the tablet easily regulated. A restaurant is fitted up in the same way; but for an ordinary private house it is sufficient to have one bell and an indicating tablet fixed in the kitchen or servants' hall, with each room enumerated upon it. I will describe an indicating tablet for a four-roomed house.

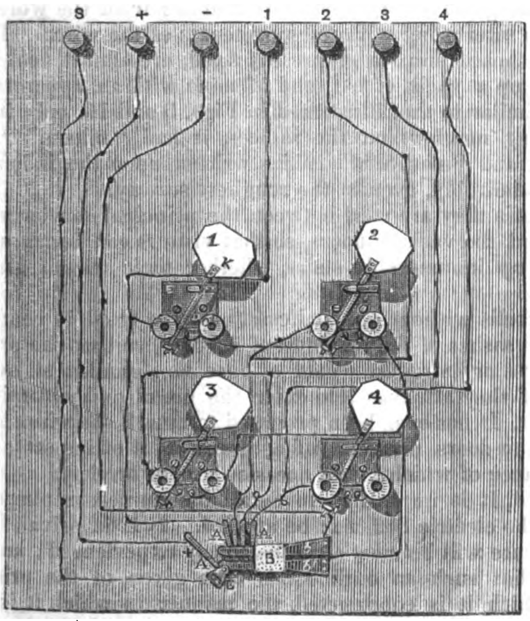

FIG. 9.

The buttons 1, 2, 3, 4 (Fig. 9) are placed in separate rooms but they are here brought close together the better to illustrate the description. The indicating tablet and bell are placed in the kitchen within easy reach of the servant. The rooms are numbered 1, 2, 3, and 4, and are so indicated on the tablet, but they can as well be designated "Dining-room," "Drawing-room," "Bed-room," and "Dressing-room," or otherwise. The tablet consists of a blackened glass frame, with four windows or openings in it, through which are shown either a white face or the numbers or names of the rooms as depicted in the above figure. The interior construction of the indicating tablet is shown in Fig. 10. (See next page.) It contains four indices, each of which is actuated by a distinct electro-magnet, shown for index No. 1 by *c* and *c'*. These indices are formed of thin cardboard or plates of mica, upon which the numbers or names of the different rooms are inscribed. They are fixed upon a magnetic needle, which moves freely upon a centre, between the two poles of the electro-magnet, and which is furnished at its lower extremity with an adjusting weight to maintain the needle balanced in any position. When a current passes through the electro-magnet from left to right the needle is thrown over in the same direction, the number of the index appearing in front of the opening of the case, and remaining there, retained by the magnetic effect of the needle upon the iron core of the electro-magnet, even after the current has ceased to flow. When, however, a current is sent in the reverse direction, the needle is restored to its original position, the number leaves the opening, the white face returns, and it remains in the position shown in Fig. 10.

The course of the current is easily traced. Take the wire No. 1 in connection with the button No. 1 (Fig. 9). It arrives at the terminal 1 (Fig. 10), and thence descends to the electro-magnet, *c*, through which it passes, and proceeds further to the spring, *b'*, which is in contact with the piece, E, and from thence it goes through the terminal, S, to the bell. Another wire is attached to this before it enters the electro-magnet, *c*, that descends to the little spring, A, which remains insulated in the normal position of the instrument. The other wires can be similarly traced, each passing through their separate electro-magnets, to the spring, *b*, and thence to the bell, and, having separate branches to distinct insulated springs, A A. The positive pole of the battery is attached to the second terminal (+), from whence it proceeds to the plate, A', which is also insulated from E and *b*. The negative pole is connected to the terminal (—), and proceeds to the spring, *b*, which is insulated and fixed like *b'* under the button, B. The battery is attached to this apparatus to restore the indices to their normal position.

The action of the instrument will now be seen. Button No. 1 (Fig. 9) is pressed—the current flows—it enters the tablet (Fig. 10) by terminal 1—it passes through the electro-magnet, *c c'*, throwing the needle over to the right, and displaying its number or name in the opening of the front case (Fig. 9). It then proceeds to spring, *b'*, through piece, E, and terminal, S, to the bell, which it rings as long as the button is held down. The finger is removed from the button, the bell ceases to ring, but the indicating number remains displayed upon the face of the tablet. The servant has heard the bell, observes the number or name of the room, and before proceeding to reply to the summons, presses the button, B, which brings *b'* into contact with A, and therefore the positive pole of the battery, and *b*, which is the negative pole of the battery, into contact with A, which is in connection of the electro-magnet, *c c*. A current is therefore sent through the electro-magnet in the reverse direction to the first current, the needle is thrown over to the other side, the indicating number is removed, and the instrument restored to its normal state. The same effect occurs with each index, and they are all actuated at the same time by the pressure of the button, B, in this particular instrument, but an alteration is frequently made which enables each number to be separately restored to its normal position. It will thus be seen that in whatever room the button is touched the bell is rung, and the number of the room is displayed upon the tablet.

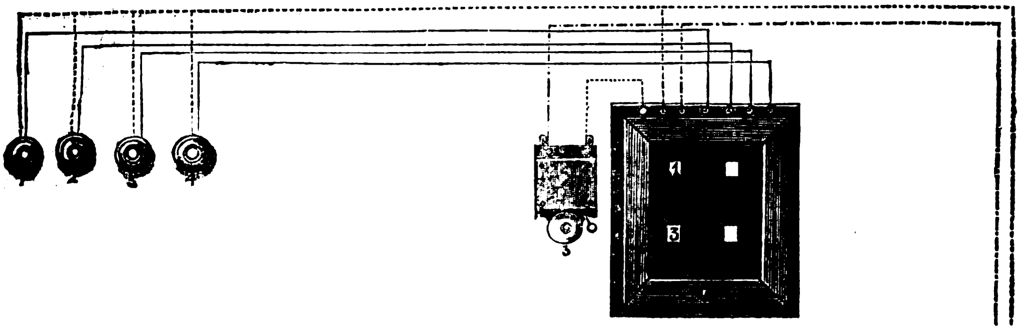

Fig. 10.

Two, three, or any number of rooms may ring at the same time. It matters not; the number is displayed upon the tablet. There is no confusion in the sound of the bell. The particular note of any particular bell is not required to be remembered; the servant has but to look at the tablet and she sees at once from whence the summons came. The tablet in Fig. 9 shows that rooms 1 and 3 have rung. These numbers will remain displayed until the call has been answered. The button at the bottom of the tablet is pressed, and the instrument is ready for another call.

It is easy to understand from the above description how the numbers of indices upon the tablet can be increased, and how one bell can be made to answer for any number of rooms. I have seen tablets with 50 numbers indicated upon them.

It can also be readily perceived how a series of rooms can be indicated on different floors or in different positions. Thus the sitting-rooms can all be shown in the butler's pantry, the bed-rooms in the kitchen. The bed-rooms can also ring, and indicate on the landing of the servants' sleeping apartments, so that attention can be gained at night. Indeed, it is scarcely necessary to relate the various modifications and arrangements that can be made. Bells can be fixed anywhere, and be rung from any spot.

I have now detailed the construction of the battery, the generation of the current, the nature of the wires destined to convey the current, the buttons that complete the circuit, and set the current in action, the bells that are actuated by the current, and the tablets that indicate the room from whence the current proceeds. The system that I have described is that called Prud'homme's, and it was partially exhibited at the International Exhibition, 1862; but considerable alterations have been effected since that period, and it is probable that we may yet see further improvements. English visitors to the French metropolis may have seen it in action at that splendid hotel, the "Louvre;" but if they have also visited that great *caravanserai*, the "Grand Hotel," they will have perceived a different system in use. It is that of M. Breguet, one of the cleverest and most ingenious of French mechanics and electricians. It is in every respect similar in principle, as regards buttons, bells, and tablets, to the system I have described; but it differs considerably in electrical and mechanical detail. The numbers are not shown upon an index moved up into position, but they are fixed. An electro-magnet releases a pointer, or marker, which falls and remains exposed over the number until replaced by the hand. Every number, or room, has its separate pointer. The "Grand Hotel" is fitted up so that the bells ring continuously; a plan which may have its advantages, but which certainly has its annoyances to those who are unfortunately located near the *bureau du service*. Breguet's system is, perhaps, the more mechanical, but Prud'homme's is the cheapest. As its economy may lead to its introduction in preference to the other, I have chosen to describe Prud'homme's rather than illustrate Breguet's system. The trembling bells have long been known in England, but they have never been extensively employed. The principal objection to their use has been the supposed trouble in maintaining the battery in order; but this trouble is pure supposition, and the battery will be found to require *infinitely* less trouble than the gas, water, or any other convenience in a modern establishment.

It now only remains to point out some of the purposes to which these bells and indicating tablets are applied.

They can be used not only to indicate rooms, but to designate men. Thus a tablet and bell can be fixed between the merchant's counting-house and his warehouse; between the manager's room, the lawyer's sanctum, or the banker's den, and the clerk's office; between the manufacturer's retreat and his workshop, with the names of clerks, foremen, or workmen inscribed upon the indices in place of the numbers. Again, they can be fixed between the private house and the stable, with the names of servants, horses, or carriages indicated upon the tablet.

In large establishments, such as Government Offices, Banks, Railway General Offices, they can be fixed between the principal offices and the porter's room, to enquire if the chief officers are in or out, engaged or disengaged.

They can be applied with great advantage on board vessels for sailors; and those who have had to do with ships and yachts know the great inconvenience that arises from the working of the ship interfering with the movements of the wires. Indeed, bells on board ship, as at present fixed, are almost nonentities. I fitted up a yacht of a friend of mine with an apparatus precisely similar to that illustrated in Figs. 9 and 10, only in place of having numbers on the indices, it had "saloon," "after," "port," and "starboard" cabins written upon the indices. It works admirably, even in the roughest seaway.

In Paris they are used between the principal concierge of an hotel and the various floors, so that visitors can learn, without puffing up innumerable stairs, whether their friends are in or out.

The bells without the indicators can be fixed in connection with the sashes of the windows of a house, so that the presence of thieves or intruders would at once be signalled all over the house, if they attempted to enter the premises by opening the windows. It has even been proposed to attach the wires leading to them to doors, drawers, safes, or any point of importance, the disturbance of which might occasion loss or anxiety.

Indeed, it is impossible to detail the numerous purposes to which the electric bell may be applied. It is in private houses that its use will be most advantageously experienced; and it is hoped that such an outline has been given of the principles upon which it is constructed, the manner in which it is fixed, and the method by which it is worked, as to enable the novice to comprehend its action, the householder to gain sufficient confidence in its working to employ it in his residence, the merchant to adopt it in his counting-house, and the sailor to fit it on board his ship.

OCEAN TELEGRAPHS.

OUR Paris correspondent lately gave an account of a plan for laying an electric telegraph cable between Europe and America. Notwithstanding the far greater distance, India will soon be fewer hours from England than America is days, so far as telegraph communication is concerned. There are two principal factors upon which the solution of the problem of oceanic telegraphy depend. One of these is the nature of the cable which is to carry the electric wire; the other is the surface over which this cable is to be laid. Naturalists tell us that ten miles in perpendicular depth of the earth's crust are within the sphere of scientific observation. The loftiest mountains are about five miles high; the profoundest seas that we have fathomed are about that depth. Sea maps show us the Atlantic Alps which, a few hundred miles to the west of Ireland, present a steep decline of some thousand feet. Three-fourths of the surface of this planet are covered with water. Our world, the dry land, is but a mere fraction of it. Yet on this one quarter on which we live there are mountains—like the Himalayas—which rear their crests far above the snow line into the region of eternal winter, to a vertical distance of more than five miles above the general surface. The peak of Dwaligiri is near twenty-nine thousand feet above the level of the sea. It is probable that in the unexplored depths of the great Pacific the ships that float on its surface are much more than five miles' distance from the land at the bottom. Curious reflection for the voyager that there is only a plank between him and perhaps ten or twenty miles of perpendicular brine. Compared with this vast ocean, the broad Atlantic, deep as it is, is probably a mere shallow. But whatever depth we take, whether five miles or one, or any fraction of a mile, every degree between that and nothing must exist, measuring from the deepest part to low water mark on either shore, where, at ebb tide, the ripple chafes against the sand and whitens it with its foam. Then, again, the existence of islands, which are only the tops of mountains, of greater or less magnitude, tell of the inequalities of surface which prevail far from the shores of the continents. Sandbanks and shallows teach the same lesson. In a word, we cannot doubt that the configuration of the earth's crust beneath the sea is pretty much what it is as we know it above the water line. Not that it is so abruptly rugged and angular. There is reason to believe that the action of the waters has rounded and smoothed off asperities Stone rocks here and there may present a sharply defined outline, but the inequalities of the general surface are probably very gradual.

But there is another cause of the presumed absence of sharp points on the submerged surface of our globe. There must be a much vaster amount of animal life in the seas which cover three quarters of this earth than there is on the dry land; and whatever lives in the waters lies down to die on the bed of the ocean. The substance brought up by soundings in deep seas invariably consists of what was once part of living organisms, swimming about, hunting other creatures for prey, and being in turn hunted itself. A shoal of herrings is several miles long, and as many broad; perhaps in deep waters it is also miles in perpendicular extent. A whale is the largest animal of which we have any authentic knowledge, and if krakens have existed, or exist now, a single specimen must contain as much animal matter as a large drove of bullocks. The remains of the inhabitants of the sea all serve to form so much padding to line the bottom of it as with a soft cushion. It is not likely, therefore, that an electric telegraph cable laid across the Atlantic would meet with perpendicular gaps and chasms of great width, from brink to brink of which it could be suspended for miles like the over-house telegraph across streets, and thus break itself by its own weight, if it were not made unreasonably ponderous. But if there were such chasms, that would be an additional reason for having it made as light as possible. To unite the maximum of strength with the minimum of weight, sufficient to make it sink at all, is the great desideratum. The greatest danger of the cable parting is in paying it out from the ship when it is being laid down. This is another reason why it should be made as light as possible—of course with a specific gravity adequate to sink it.

Now, in the plan alluded to above, it is maintained that a copper wire conductor, covered with a Manilla hemp insulator, is the lightest cable that can be made, and is yet quite heavy enough to sink, and strong enough to hold together and bear any strain to which it will probably be subjected. The waters of the sea, at a comparatively very short distance below the surface, are perfectly still, even in the most violent tempest. It appears that in our Channel—a mere ditch compared with deep seas—the telegraphic cables at the bottom are never disturbed by tides and currents, much less by agitation produced by storms on the surface, but only by trawls and anchors. Of course there may be marine monsters at the bottom of the great ocean of which we know nothing, and the wider the extent traversed by the cable the greater the chance of disturbance from huge living creatures. If the cable, in any part of its course, were to pass from one submarine precipice to another, like the over-house telegraphs across the Thames, the chances of great fish coming into contact with it and snapping it asunder would be increased. Still no strength that we could give it by means of iron wire could enable it to stand this shock any better than a simple coating of hemp. The weight of the cable intended to be laid across the Atlantic is described as so great that there is no ship in the world, except the Great Eastern, that will carry it. Its cost, too, is represented as being quite as heavy as the specific gravity. The two thousand three hundred and odd miles of it, at £300 a mile, the estimated cost, will amount to near three quarters of a million sterling. If the statement before us be accurate, there have been several failures of much shorter cables than this, but made on the same principle, through their great weight rendering them unwieldy and unmanageable. It seems that the Falmouth and Gibraltar cable cost £300 per mile, and when made it was declared to be useless. It was impossible to lay it down, its weight being so great as to break of itself. So, after lying idle for a couple of years, it was laid down in shallow water along the Barbary coast, between Malta and Alexandria. The Atlantic, the Red Sea, and the Algiers cables are all stated to have destroyed themselves through their too great weight. If these data be sound and the inference deduced from them valid, it is not difficult to foresee what fate awaits the Atlantic cable, which the Great Eastern is to lay down in 1865. This is a subject well worth the attention of the scientific world.—*Morning Post.*

THE INTERNATIONAL EXHIBITION, 1862.

(Continued from page 199.)

C. F. Varley, M. (United Kingdom, 2,981), exhibited an arrangement by which the position of a fault of insulation, either on a land-line or in a submarine cable, can be determined with very great accuracy, whenever the fault can be included in a complete circuit starting from, and returning to, the testing station, and everywhere insulated except at the fault. On land-lines this condition is almost always attainable by joining two of the line wires at a station beyond the fault. In submarine cables the condition can always be fulfilled before the cable is laid, but after submergence the cable must contain two insulated conductors to allow the application of the test. The method adopted by Mr. Varley is especially excellent, inasmuch as the uncertain resistance of the fault does not vitiate the test, which will give one constant result whether this resistance be great or small, constant or continually varying, during the experiment.

A differential galvanometer and a set of resistance coils are the only instruments required. The resistance of the whole circuit is first determined by connecting the two poles of a battery to the two ends of the line circuit through one coil of the differential galvanometer, while the two ends of the resistance coils are also connected with the two poles of the same battery through the other coil of the galvanometer. When the galvanometer needle has been brought to zero by adjusting the resistance coils, the resistance of these coils will clearly be equal to that of the complete line circuit, quite independently of the fault, since the earth forms no part of either of the balanced circuits. Let us call this resistance r.

After determining this resistance the connections are altered, so that one pole of the battery is put to earth, and the other pole connected with the one pair of ends of the two differential coils; the other ends of these coils are then connected with the two ends of the line circuit respectively, and the resistance coils introduced into the line circuit between the fault and that differential coil which is nearest to it. Let the resistances of the two sections of the line between the testing station and the fault be called x and y respectively, and let y be the smaller of the two. Then, if the resistance of the coils in their new position be adjusted until the galvanometer needle be again brought to zero, and this new resistance be called R, we have the following relation experimentally determined:—

$$x = y + R.$$

The resistance of the fault is included equally in the two balanced circuits; and, therefore, whether great or small, constant or variable, does not interfere with the above relation. Moreover, by the first test, $x + y = r$, and eliminating x from the two equations, we have

$$y = \tfrac{1}{2}(r - R).$$

If r and R be expressed in miles of the conducting wire, y will also be expressed in miles, and will tell the observer directly the distance of the fault. It should be observed that, since r given by the first test is equal to twice the resistance of the line between the stations, and that R, given by the second test, is equal to twice the resistance of the line between the far station and the fault, $\frac{R}{r}$ is, therefore, equal to the fraction which the distance between the far station and the fault is of the whole distance between the stations.

In Mr. Varley's apparatus the change of connections required for the double test is made very simple by the depression of a key, so that the whole operation is mechanical, and the test can be, and actually is, made by uneducated workmen.

After this apparatus had been exhibited to the jury, the writer believes that it was removed from the building.

2. *Resistance Coils.*

In order that different observers should be able to compare the results of their separate observations, it is clearly necessary that they should use the same unit of resistance, or should at least know accurately the relative value of their several units. No two sets of resistance coils exhibited are alike, and it is, therefore, thought useful to give the annexed table of the relative values of the several

Table F.—Relative Values of various Units of Electrical Resistance.

Description.	Name.	Absolute $\frac{\text{foot}}{\text{seconds}} \times 10^7$	Thomson's unit.	Jacobi.	Weber's absolute $\frac{\text{metre}}{\text{seconds}} \times 10^7$	Siemens (Berlin)	Siemens (London)	Digney.	Bréguet	Swiss.	Matthiessen.	Varley.	German Miles.	Observations.
*Absolute $\frac{\text{foot}}{\text{seconds}} \times 10^7$ electro-magnetic units (new determination)	Absolute $\frac{\text{foot}}{\text{seconds}} \times 10^7$	1·000	0·8750	0 4401	0·3048	0·2912	0·2878	0·03028	0·02870	0·02687	00·2062	0·01094	0·004878	Calculated from Weber's new determination of the absolute $\frac{\text{metre}}{\text{second}}$ *vide* fourth column; $1 \frac{\text{metre}}{\text{second}} = 3{\cdot}281 \frac{\text{foot}}{\text{seconds}}$.
Absolute $\frac{\text{foot}}{\text{seconds}} \times 10^7$ electro-magnetic units (old determination)	Thomson's unit.	1·143	1·000	0·5029	0·3483	0·3328	0·3289	0·03455	0·03279	0·03071	0·02357	0·01251	0·005574	From an old determination by Weber; should have agreed with first column.
Twenty-five feet of a certain copper wire, weighing 345 grains	Jacobi.	2·271	1 988	1·000	0·6925	0·6618	0·6540	0·06869	0·06520	0·06106	0·04686	0·02486	9·01108	No measurement made—ratio between Siemens (Berlin) and Jacobi, taken from "Weber's Galvanometrie."
Absolute $\frac{\text{metre}}{\text{seconds}} \times 10^7$ electro-magnetic units determined by Weber (1862). . . . One German mile = 8,238 yards of iron wire $\frac{1}{6}$ in. diameter (temperature not known)†	German mile.	205·0	179·4	90·22	62·48	59·71	59·00	6·198	5·882	5·509	4·228	2·243	1·000	From coils exhibited by Messrs. Siemens, Halske, & Co.†

* *Note, June*, 1863.—From unpublished experiments made by the Committee on Electrical Standards of Resistance appointed by the British Association, it appears that the true value of the absolute unit lies between the two values.

† Messrs. Siemens do not now manufacture coils with this unit, which has been abandoned by them in favour of the mercury unit given above.

N.B.—The statute mile of No. 8 iron wire frequently referred to in the course of the report was equal to 0·48 of Mr. Varley's units = 1·33 Digney's kilometres of iron wire 4 millimetres diameter.

resistance units exhibited, and also of some others known to have been extensively used. The comparisons were made by the writer with Messrs. Siemens' instruments expressly for this report. It is hoped that before long some common standard will be universally adopted.

The unit of the resistance coils placed second in the table, and shown by J. White, M., Glasgow (United Kingdom, 3,012), was chosen by Professor W. Thomson, and was intended to approximate to a decimal multiple (10^7) of Gauss' and Weber's absolute units based on feet and seconds, irrespective of the special qualities of any particular material. The advantages of the absolute unit have been briefly alluded to in the introduction. Owing to some error (probably in an old determination by Weber), Mr. White's coils, although extremely well adjusted one with another, are far from presenting the desired approximation, if Professor Weber's latest determination of the $\frac{\text{metre}}{\text{seconds}}$ standing forth in the table may be relied on. Had the agreement between Professor Weber's and Mr. White's coils been complete, Weber's unit given in the above table would have been equal to 3·281 White's units (the ratio of the foot to the metre), instead of 2·871. The absolute $\frac{\text{foot}}{\text{second}}$ multiplied by 10^7 calculated from Weber's last determination is given first in the table. The unit marked on the coils shown by Mr. White is 10^8 times the absolute $\frac{\text{foot}}{\text{second}}$, but to avoid confusion the value in the table is given at 10^7, otherwise the $\frac{\text{foot}}{\text{second}}$ would have appeared larger than the $\frac{\text{metre}}{\text{second}}$. The multiple 10^7 of the $\frac{\text{metre}}{\text{second}}$ (given fourth in the table) was chosen as that recommended by the committee on electrical standards of resistance appointed by the British Association for the Advancement of Science.

The relative value of Weber's $\frac{\text{metre}}{\text{second}}$, as compared with Siemens' and Thomson's units, was obtained by the direct measurement of a coil sent by Professor Thomson to Professor Weber, who determined its resistance in absolute measure. The results in the table do not agree within 2 per cent. with the value published by Weber of Siemens' unit. All these discrepancies show the necessity of much greater accuracy than has hitherto been arrived at in measurements of this kind.

The various copies of Jacobi's unit (not exhibited) agree very badly; the values in the table (third column) are taken from the value of Jacobi's unit, published by Dr. W. Siemens, as compared with his own unit. Professor Jacobi's unit is the resistance of a certain copper wire twenty-five feet long, weighing 385 grains (temperature unknown).

Siemens & Halske, Berlin, M. (Prussia, 1,413), exhibit coils based on an unit expressing the resistance of a metre of mercury of one millimetre section at the temperature of melting ice. Each set of coils exhibited by the London and Berlin firms is adjusted with an accuracy of one per thousand, but those exhibited by the two firms differ from one another by more than 1 per cent. Messrs. Siemens suggest that this difference may be due to an alteration in the German silver wire of which the coils are made; but it seems at least as likely that the mercury standard has not been maintained or reproduced with exactitude. This opinion is somewhat supported by the fact that Mr. White's coils, although they have been in constant use for three years, are still adjusted with about the same degree of accuracy as Messrs. Siemens' (except one coil in which an error of about 1 per cent. occurs). If, therefore, the resistance of these coils, which are also made of German silver, has changed, the resistance of every coil (but one) must have changed in exactly the same proportion—a most unlikely result. On the other hand, Messrs. Siemens inform the writer that the two coils now exhibited by the two firms were really made by the Berlin firms at about the same time. They suggest that, when compared by the writer, they may not have been at the same temperature; but precautions were taken to prevent mistakes from this cause, and a difference of temperature of about 45° Fahrenheit would be required to account for the difference of resistance observed.

MM. Digney's, M., Bréguet's, and the Swiss resistance coils are all intended to represent the resistance of a thousand metres of iron wire four millimetres in diameter, such as is used for telegraphic lines abroad. The three sets of coils differ widely from one another. Messrs. Digney's coils are, however, adjusted, one with another, with no greater error than 0·5 per cent. The coils by the two other makers were very indifferently adjusted, and the values given in the table are only the means of widely discrepant results.

Dr. A. Matthiessen has adjusted a coil (not exhibited) expressing the resistance of a standard mile of chemically pure annealed copper wire one-sixteenth of an inch in diameter, at the temperature of 15·5° centigrade. This resistance is very different from that of a mile of any commercial copper, and the various commercial coppers differ too widely from each other to allow any approximate ratio to be named between them and pure copper. It may be said, however, that the specific resistance of copper selected for telegraphic cables is generally about 20 per cent. higher than that of pure copper. Dr. Matthiessen does not propose this coil as an unit, but the writer thought that its value would be found useful.

Mr. C. F. Varley's unit is the resistance of one particular piece of copper wire one-sixteenth of an inch in diameter and one mile long. The values in the table were obtained from measurements of coils exhibited by Mr. Varley.

A second unit used by Messrs. Siemens & Halske on German railways was intended to express the resistance of a German mile (4·68 English miles or 8,238 yards) of iron wire one-sixth of an inch in diameter (No. 8 B. W. G.); this unit is no longer used by the firm.

A note at the foot of the table gives the value of the statute mile of No. 8 iron wire, occasionally referred to in this report as a rude standard of comparison, conveying a practical idea to those not conversant with the conception of an unit of electrical resistance.

(To be continued.)

THE PERSIAN GULF TELEGRAPH.

To the Editor of The Times.

Sir,—I observe a paragraph in your impression of to-day, to the effect that Sir Charles Bright has advised you of the completion of the Persian Gulf Telegraph. I have before observed Sir Charles Bright's name prominently mentioned in connection with this great undertaking. Far be it from me to attempt to diminish in any way the great service rendered by Sir Charles Bright in laying this most important telegraph. However, I do not think it just, nor do I think that Sir Charles Bright would wish that his should be the only name brought so prominently before the public in this matter. The gentleman who has had the whole management and entire superintendence of this most important work from the beginning, and under whom Sir Charles Bright is at this moment so ably acting, is Lieut.-Col. Patrick Stewart, R.E. The *Times* has often before done ample justice to the merits of Col. Stewart; but there are many persons who have seen these later paragraphs to which I especially refer, who may not have seen your former account of Col. Stewart's services in connection with the Persian Gulf Telegraph. Only last week the remark was made to me, "Sir Charles Bright seems to have the chief superintendence of this telegraph, as the telegrams come from him." To remove that erroneous impression is my reason to trouble you with this letter.

Palmam qui Meruit Ferat.

We reprint the above letter,—at the same time we cannot help thinking but that Col. Stewart may well exclaim, "Save me from my friends!" As we have published several communications received from the East respecting the labours of Col. Stewart and those connected with him in the great undertaking, we believe that our readers will find that in those reports Col. Stewart's name stands the most prominent. The information conveyed in the paragraph which appeared in the *Times* on 22nd ult., appeared in this Journal on the 16th ult., just six days in advance of the *Times*. Our information was not derived from Sir Charles Bright, but from a telegram said to have been received from Col. Stewart at the India Office. The success which has crowned the labours of Col. Stewart in the laying of the Persian Gulf Telegraph redounds greatly to his honour; and we are sure that no one will be more ready to recognise the valuable services rendered by Sir Charles Bright and his experienced staff than Col. Stewart himself.

These attempts to engender professional jealousy are to be deprecated, and the writer in the *Times*, had he been better acquainted with the history of the manufacture, testing, shipment, and the submersion of the Persian Gulf submarine cable, would not, we believe, have had reason to complain of the supposed assumption of undue merit in connection therewith by Sir Charles Bright and his staff. The public, who received with unbounded satisfaction the intelligence of the successful accomplishment of the great and important work, will not lack discrimination to award the merit to whom it is due.—[Ed. T. J.]

The following additional communication on the subject of the above telegraph appeared in the *Times* of the 28th inst.:—

To the Editor of THE TIMES.

SIR.—In your impression of the 25th inst. a correspondent claimed attention for the services of Col. Stewart, in connection ith the Persian Gulf Telegraph, and I think you will agree with me, that the earlier services of Mr. W. P. Andrew, the persevering and consistent advocate of the telegraph and the railway by the Euphrates route, should not be forgotten. Mr. Andrew predicted in your columns, so long ago as the 26th of May, 1858, and on several other occasions, the entire success that would attend the establishment of telegraphic communication by the Euphrates and the Persian Gulf, and the failure of the attempt by the Red Sea, and at the time when those who were considered great authorities were arrayed against him. All the essential circumstances connected with the Red Sea Telegraph have come within my knowledge, and Mr. Andrew certainly did not overrate the physical difficulties of the route, but he did not foresee the moral ones, which in themselves would have been quite sufficient to have caused the failure of that line had the physical circumstances been as favourable as they have proved the contrary. With regard to the Persian Gulf, I will only add my conscientious conviction that, had the conduct of this affair been left to Mr. Andrew, a large saving would have been effected in cost, or greater efficiency attained. This opinion I offer deliberately, from actual knowledge.

I am, sir, faithfully yours,

24, Great George-st., Westminster, GEORGE P. BIDDER.

April 27th, 1864.

DABOLL'S FOG SIGNAL.

A VERY interesting Report has just been published, by order of the House of Commons, containing an account of all the experiments made under the direction of the Trinity Board Corporation, with a view of testing the different plans for fog signals in connection with the dangerous navigation of the Gulf of St. Lawrence and elsewhere. It appears that the Trinity Board Corporation, after a series of successful trials with the Daboll's Signal against a Bell and Holmes' Steam Horn at Dungeness Point, has determined, with the approbation of her Majesty's Government, to purchase one of Mr. Daboll's apparatus, with the view of instituting additional experiments as to its applicability for the purpose of signalling on dangerous coasts. The following are the Reports of the Committee of the Elder Brethern, who tested the power of Mr. Daboll's Fog-Horn at Dungeness in the months of December and January last. Our readers will at once perceive how, by the adoption of the telegraphic alphabet of Morse to the duration of the blasts of the trumpet, communication could be easily effected between the light or signal houses and vessels at sea both by night and day. It has long been a matter of surprise that the electric telegraph has not been adopted as an auxiliary to our system of lighthouses along our coast.

REPORT OF A COMMITTEE OF THE ELDER BRETHREN WHO TESTED THE POWER OF DABOLL'S FOG-HORN, AT DUNGENESS.

The fog-horn is placed about 500 feet from the low-water line, and 350 from that of high-water spring tides, and 15 feet above the latter; the lighthouse is distant 270 feet in a north-by-west compass bearing. The sound is emitted from a trumpet placed in about a north and south direction, and eight feet above the shingle; it is 4 feet 6 inches in length, by a diameter of 3½ inches at the smaller end, and that of 1 foot 9 inches at the mouth, which projects about 2 feet 6 inches from the southern end of the corrugated iron building erected over the apparatus.

The following programme of experiments was carefully carried out, viz.:—

	PERIODS.					
	1.	2.	3.	4.	5.	6.
	H. M.	H. M.	H. M.	H. M.	H. M.	H. M.
Daboll's horn sounding . . .	12 0	12 15	12 30	12 45	1 0	2 to 3
Holmes' horn sounding at the lighthouse	12 3	12 18	12 33	12 48	1 3	—
Bell sounding at the lighthouse	12 6	12 21	12 36	12 51	1 6	—
All the above together for two minutes	12 9 to 12 11	12 24 to 12 26	12 39 to 12 41	12 54 to 12 56	1 9 to 1 11	—

The sound from Daboll's horn continues for four seconds, with intervals of 12 seconds, and which regularity the committee consider would render it a distinct fog-signal from that used by any vessels. Holmes' trumpet gives a continuous sound, and the bell strikes thirty times each minute.

The committee, consisting of the Deputy Master, with Captains Redman, Were, and Nisbet, accompanied by Professor Faraday, embarked from Dover in the "Irene," at 9 a.m. on the 17th November, 1863, and proceeded to Dungeness, the wind moderately fresh from the westward, and continuing so all day.

At 10.50, anchored to the eastward of the Ness, and informed Mr. Daboll that should he not feel perfectly satisfied with the manner in which the experiments were carried out, he was to make the same known to the committee by hauling down the colours at the lighthouse, at 3 p.m.

At noon, when distant two miles, by measurement by angles, from the lighthouse, it then bearing north, the experiments of the first period were made, during which time Daboll's horn was heard. Steamed in on the same line of bearing to 1½ miles from the lighthouse; and during the experiments of the second period Daboll's horn was heard, and that a good sound. Steamed in on the same line to one mile from the lighthouse, and during the third period Daboll's horn was heard well, and only a surmise as to any other sound reaching the vessel.

On the same line of bearing steamed in to within half a mile from the lighthouse when, during the fourth period, Daboll's horn was heard well. The bell also gave a good sound. Holmes' horn was only faintly heard; and when from 12.54 to 12.56 all the instruments were sounding together, the latter was heard in the intervals as a mere rumbling sound.

The experiments of the fifth period were heard at the same position, and gave similar results. When passing in from the lighthouse, bearing north to west, the committee observed the sound of Daboll's horn to sensibly diminish in power as the steamer passed from the axis of the trumpet to its outside edge.

At 2 p.m. the lighthouse bearing east, distant two miles, and directly to leeward of the vessel, Mr. Daboll's horn commenced to sound alone. This sound was not heard on that line of bearing until the vessel was only one-third of a mile from the lighthouse; but when crossing to the line of having the lighthouse to bear north, the sound increased in power as we approached the axis of the trumpet; and on that line of bearing the sound was distinctly heard at the distance of 2¼ miles.

At 3.15 p.m., observing the colours at the lighthouse still exhibited, the committee proceeded to Dover, when, passing to leeward of the lighthouse, the sound from Daboll's horn was heard at a distance of 4 miles or 4½ miles.

On a careful reconsideration of the result of the above experiments, made with a moderately fresh westerly wind blowing, and that the Point of Dungeness is one especially requiring fog-signals, the committee recommend to the Board that Mr. Daboll's apparatus be purchased for the sum of £500, and retained at Dungeness.

(Signed) WILLIAM PIGOTT, Deputy Master.
G. J. REDMAN.
T. N. WERE.
E. P. NISBET.

(To be continued.)

THE ATLANTIC TELEGRAPH.

IRON and india-rubber—zinc, acid, and copper—and the world is to be revolutionised! There are to be new currents in the ocean, and the torpedo is to be outdone in his own element. The dead men's bones and heaps of gold on the floor of the great deep are to be traversed by a line which goes out from the British Isles and breaks not till it reaches the shores of the New World. A large instalment of the earth's girdle is to be stretched through the abyss next spring. The biggest ship in the world—and the most unlucky since the days of the Flying Dutchman—is to have one more chance of redeeming its character. The Gutta-Percha Company and Messrs. Glass, Elliot, & Co. have gone through the transmuting process of the Joint-stock and Limited Liability Acts, and, having been duly amalgamated, now stand out before the world with the unmusical title of the Telegraphic Construction and Maintenance Company. Let us hope that this quaint yet business-like appellation will be happily verified in the case of the great Atlantic cable, and that the Anglo-American telegraph, being duly constructed, will be effectually "maintained." Further, let us hope that the said cable will also "maintain" the dividends to be anticipated by the shareholders in the Atlantic Telegraph Company, at whose instance Messrs. Glass & Elliot have taken up the contract, which, of course, now merges in the operations of the new amalgamation just referred to. If the Great Eastern does her duty in this important enterprise, we will forgive her all the naughty tricks and prodigious extravagances of which she has been guilty, and pronounce her past offences for ever expurgated. On the contrary, if she goes rolling about, broadside on, and upsets

everything, we shall vote the Leviathan an incorrigible plague and a scourge to the human race. Capitalists have already flung a hillock of gold into the sea, in a fruitless attempt to link the New World to the Old in an electric chain. Another hillock is growing up, and simply to throw one after the other would be something too provoking, even for the patience of that most enduring creature, the modern shareholder. Let us hope for the best. If the Great Eastern does her duty on the forthcoming occasion, £50,000 in paid-up shares of the Atlantic Telegraph Company will reward the proprietors, and the glorious results of electric communication between the two terrestrial hemispheres will delight the world. The "United States" may then be taken to represent —not a mere American federation—but the relationship subsisting among all the civilised nations of the earth.

Surely our modern science will accomplish this most desirable feat? True, it is "no narrow frith" which our engineers propose to cross. But the skill which can bore a tunnel through the Alps, and build such a monster of the deep as Brunel's gigantic ship, can lay a cable at the bottom of the sea, even though the line be some thousand miles in length. War is doing wonders. Big guns are crashing through iron and steel, and the thunders of the battle-field and the siege outvie "the bolts of heaven." The triumphs of peace must be extended. Let the "batteries" of the electrician contend with those of the warrior. Let the messages of commerce and trade, of friendship and congratulation, supersede the missives of war and the dispatches of contending generals. Let us hope that the deep-sea telegraph will be "a bond of peace." It is not England's fault if belligerent murmurs traverse the Atlantic.—*Standard.*

MR. COOKE'S PAMPHLET OR SKETCH OF 1836.

(*Continued from page* 200.)

Our readers are now in possession of the whole of Mr. Cooke's sketch, with the exception of a few *Notes*, which we now append. The pamphlet is a valuable contribution to telegraphic literature. It shows that the writer had bestowed much thought and labour on the subject, and at a time when but few were ready to receive his project as capable of practical realization. We will here quote the opinions expressed by a gentleman of high scientific attainments after perusing the sketch in January, 1837. Dr. Reynolds of Liverpool, writing to a mutual friend, observes, "He (Mr. Cooke) appears to me to underrate the practical difficulties of maintaining a wire extending for many hundred miles in a state of perfect integrity and electrical insulation; and unless he has two wires of communication, he would, I conceive, be liable to the inconvenience of the parties at each extremity signalling at the same moment of time, and the effect being thus destroyed." Dr. Reynolds by no means stood alone in his "doubts and perplexities" as to the future of the wonderful invention. Professor Daniell, who had for years witnessed the profound researches and investigations of Professor Wheatstone, exclaims, "I had followed, as you well know, all your (Professor Wheatstone's) experiments from the beginning, and was intimately acquainted with both the principle and construction of your apparatus; but, nevertheless, when I saw it in action upon the Birmingham railroad, I was struck as with something quite new. The facility with which I could myself immediately read signals communicated from a distance; and the simplicity of the means by which I saw you reply to them, and which I felt that I could master in five minutes, produced in me something of the *feeling of magic.*" Such were few of the incidents in connection with the early introduction of electro-telegraphy. It has been the habit of late, on the part of some of our writers, to characterise the electric telegraph as a "child of many fathers," and to ignore to too great an extent the indefatigable labours and the ingenuity of Messrs. Cooke and Wheatstone, in despite of the emphatic opinions expressed by the late Sir M. Isambard Brunel and Professor Daniell, that "whilst Mr. Cooke is entitled to stand alone as the gentleman to whom this country is indebted for having practically introduced and carried out the electric telegraph as a useful undertaking, promising to be a work of national importance, and Professor Wheatstone is acknowledged as the scientific man whose profound and successful researches had already prepared the public mind to receive it as a project capable of practical application, it is to the united labours of two gentlemen so well qualified for mutual assistance that we must attribute the rapid progress which this important invention has made during the five years since they have been associated." We have already observed that the history of the electric telegraph has been but imperfectly told, and that amongst the many thousand of individuals now connected with telegraphic undertakings, as directors, shareholders, and employés, there are but few, comparatively speaking, acquainted with the history of the most important invention of modern times—an invention which day by day becomes more appreciated as the speedy promulgator of human thought, its joys and its sorrows, its hopes and its fears, and in facilitating the social, commercial, and political exigencies of the civilized world.

NOTES.

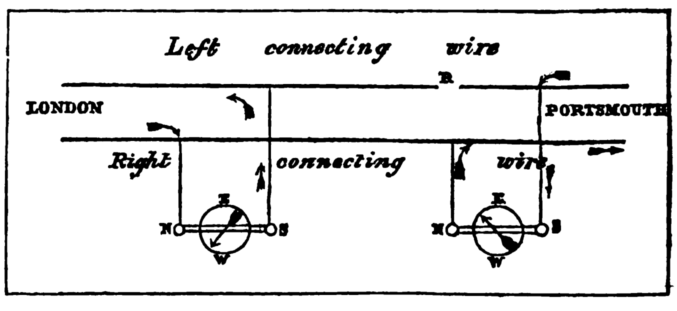
I. This instrument is capable of representing in rapid succession sixty letters, figures, and symbols, with a distinctness which admits of no mistake. (See page 190).

II. Any number of instruments may be attached to the same conducting wires. Hence, if telegraphic intercourse is to be established between two distant places, the wire laid down for this purpose may be connected with an instrument at every town which it visits throughout its course. In such combinations, whatever symbol is represented on any one instrument immediately presents itself on all the rest. (See page 190).

III. The following plan for the construction of a conducting trough is recommended by the projector, as the cheapest and most durable which has occurred to him, offering at the same time an effectual mode of isolating the wires and of protecting them from decomposition. He proposes that the wires be laid in separate channels formed along the surface of narrow slips of baked wood, and covered in with a thin lath of the same material, and that this case be inserted into a trough of thick semicircular draining tiles about three or four inches in diameter, the space between the wood and tile being filled with waterproof cement, the whole may be guarded above by a flat tile and buried from eighteen inches to two feet in the ground. Through large towns, where the streets are frequently disturbed for the laying of gas or water pipes, iron pipes (the wires being isolated by wood) might be preferable. (See page 190).

IV. As no interference with common or rail roads is permitted, except under the direction of the authorities, timely notice to the proper quarter would be given, if the repairing of a bridge, the laying of drains, the lowering of a hill, or any other work likely to disturb the wires, was about to take place, when a new or temporary line of wires would be completed along the disturbed space before the old one was removed. (See page 190).

V. That the use of this instrument, which we will call a "detector," may be more fully understood, the following explanation and diagram is subjoined. The detector resembles a small pocket compass, with a coil of copper wire or a multiplicator fixed across the dial plate from north to south, terminating at the extremities in cups for mercury; when used, the dial plate is adjusted to the magnetic meridian, so that the needle, when at rest, becomes parallel to the wire. If a current of positive electricity be passed along the wire in the direction of N S, the north pole of the magnetic needle, will be deflected towards the west; if in the opposite direction, the effect on the needle will be reversed, the north pole of the needle deviating to the east; let L P be two places between which the connection has been broken off at the point, R. The telegraphic instruments at both places are so arranged that upon being set the positive currents tend to flow from each telegraph in the direction indicated by the arrows. Whenever the detector is applied to the branch wires, it completes the galvanic



circuit either with the telegraph at L or P, according to the side of R, on which the experiment is made; and as the right branch wire from L is always placed in connection with the north cup, and the left branch wire with the south cup of the detector, it is manifest from what has been said that, so long as these experiments are made between L and R, the deviation of the north pole of the needle will be westerly, and that it will be easterly on the other side of R, thus indicating the direction of the injury. (See page 199).

VI. In Government business, the delay occasioned by transposing the signals might be avoided, and further advantages secured when the despatches passed through confidential hands only, by having a distinct apparatus, secured from access by lock and key, in connection with the general line of wires, in which the order of the symbols might be differently

arranged, so that the signals represented on the other instruments, through which the communication passed when the Government telegraph was working, could have no connection with the sense of the Government dispatch, which would nevertheless be expressed in the ordinary numbers, and in reference to the published signal. If any further precaution were required, a signal-book differently numbered, or a supplement to the published one, containing names, important expressions, such as "war," "riot," "military," &c., might be used for further security, or a trifling periodic change in the arrangement of the symbols, requiring only a minute or two for adjustment, would baffle the most skilful decipherer. (See page 200).

VII. The periodic announcement of this and other great markets would occupy but little time, for by allotting to certain important intelligence of frequent occurrence the lower numbers (say from 10 to 99, which require only two signals to express, and which would be readily recognised in practice), on the expected signal appearing about the usual time, the clerk would take up a printed form and fill up the blanks as the signals appeared. The order in the details of each report would be uniformly observed, as they would be given from a similar printed form filled up by a responsible person. (See page 200).

THE UNITED KINGDOM AND THE BONELLI TELEGRAPH COMPANIES.

The daily papers have, for some weeks, been the exponents of somewhat angry discussions between the above companies. The question at issue seems to be the relative merits of now two well-known instruments, namely, the *Bonelli*, and the *Hughes*.

The United Kingdom Telegraph Company insists that the *Hughes*, their sole property, is capable of transmitting, in a given time, a greater number of messages, employing only one wire, than the instrument of the Bonelli Company, which requires five wires. The first-named company, however, stipulates that as it uses both for the *Hughes Printer* and the *Morse Ink-writer* only one wire each, the result, in every case, must be multiplied by five for work performed and cost of performing it, so as to equal the five wires used by the Bonelli Company, or, as we understand it, that one of Bonelli's instruments is challenged to work against five of Hughes's and Morse's. We shall look forward for the result of the competitive trial with considerable interest, as not only likely to establish the respective merits of two very valuable and ingenious instruments, but as a step towards extending the advantages of telegraphic communication. We believe that both instruments would find ample remunerative employment were their adoption to become more general. We have had several opportunities of witnessing the marvellous rapidity and certainty with which communications are effected by means of both systems.

We append the proposals submitted by the United Kingdom Telegraph Company as the basis for the competitive trial, reserving our comments for the present:—

United Kingdom Electric Telegraph Company (Limited).

Proposal for a Competitive Trial of the system used by the United Kingdom Electric Telegraph Company and that of the Bonelli Telegraph Company, between Liverpool and Manchester, and for the proof that the necessary use of five wires constitutes an impracticability for a commercial-remunerative system:—

That the trial shall be of such a character as to afford really satisfactory evidence of the merits of the respective apparatus.

That, to attain this, it is necessary to try the apparatus in all weathers, for correct and useful purposes, and under similar circumstances to those under which ordinary telegraphic correspondence is performed.

That the trials should, therefore, extend over a period of at least fourteen days, so as to afford proof that the instruments continue in reliable and regular working order.

That any derangement in the system under trial is not to be corrected by recourse being had to any other system for an exchange of instructions, or other communications.

That each system shall be clearly explained before the trial, and the whole of the apparatus used be fully shown and described; the mechanical, electrical, and chemical arrangements gone through; and that all these points shall be taken down in writing, and no departure from them be allowed.

That any change or increase, or diminution of electrical or chemical power may be made.

That the basis performances of the Bonelli apparatus, published in the prospectus of that Company, be taken as a fair basis of work to be performed.

That the statement made in the same document, as to the Bonelli working between Liverpool and Manchester, be also taken and gone into as [a fu]rther basis.

[T]hat each Company shall take the number of wires required to work one apparatus of each kind and no more, although that number of wires may be reduced if practicable.

That an account of the number of messages received and sent for the public between Liverpool and Manchester for the past six months by each Company, and the time occupied in their preparation and transmission, shall be delivered as proof of the actual electrical working capabilities of the two Companies' systems in positive practical work, the object of a trial being to arrive at practical results.

That in like manner the staff employed to perform the above work, and the expenses incurred, shall also be taken as a further practical business-like proof of the relative cost of the different systems.

That for the fourteen days named several hundred messages per day shall be exchanged by each Company between Liverpool and Manchester, on each system employed by such Company.

That the messages sent by both Companies shall be, in all cases, fac-similes.

That news expresses shall also be sent, as above, of several columns of the ordinary description of matter forwarded by reporters for the press.

That neither Company shall be made aware beforehand of the number of messages to be sent, nor of the amount of press matter to be forwarded.

That messages and press matter shall all be treated exactly as if to be made use of, and shall be preserved and noted accordingly.

That the working from each end shall be from the same room, each Company providing its own wires and clerks.

That the staff employed and wages paid shall be declared beforehand, and be strictly adhered to.

That the working shall be before and after the most busy hours of the day, as may be arranged.

That as the United Kingdom Company uses for both the Hughes Printer and the Morse Ink-writer only one wire each, the results in each case be multiplied by five, for work performed and cost of performing it, so as to equal the five wires used by the Bonelli Company.

That each message or express shall be timed when it is begun and when finished, to date from the beginning of either Company's operations to prepare for its transmission. That each Company will be expected to work up to the maximum of its respective system.

That each system shall also be tried upon extended lengths of wire, in bad weather, as a proof that the Bonelli system can or cannot work under such circumstances.

That the same description of proofs be gone through as for the short line between Liverpool and Manchester.

That for these latter experiments the United Kingdom Company allow the Bonelli Company to make use of the United Kingdom Company's wires, or the Bonelli Company may arrange with any third company.

That for the purpose of proving the impracticability of a five-wire system, the United Kingdom Company shall go fully into the cost of such a system, the capital required, and the practical difficulties in its way, and that the Bonelli Company shall in like manner be called upon to prove its practicability, the number of wires to be applied on each circuit, the staff to be used, the offices, &c., and the general cost of establishing and working such a system in every particular. These statements and calculations on both sides to be in writing.

That for this purpose the available capital of the Bonelli Company, after all liabilities are met and discharged, including patent rights, if any, shall be declared, as the capital available and required are essential elements of the question.

That statements having been made to the effect that the Bonelli apparatus was working in France, the Bonelli Company be invited to show where it is at work, or if it has been adopted, and that the United Kingdom Company may show, in like manner, if the Hughes is adopted officially by the Government of France, and if its use is being extended there and elsewhere.

That the Worshipful the Mayors of the respective towns or the Presidents of the Chambers of Commerce, or some other equally independent parties, be chosen to arrange with the Companies the details of the work to be delivered to the Companies, and to record the results.

Magnetic Storms.—Did any doubt remain of the electrical character of the *aurora borealis*, it would be removed by the phenomena presented by the needles of the telegraph, and often by the bills during the prevalence of this meteor. At such times the needles move just as if a good working current were pursuing its ordinary course along the wires; they are deflected this way or that, at times with a quick motion; and changing rapidly from side to side many times in a few seconds, and at other times moving more slowly and remaining deflected for many minutes with greater or less intensity, their motions being inconstant and uncertain. These phenomena have occurred less frequently on the part of the line between Reigate and Dover, which seems nearly east and west, and on the part between London and Reigate, which is nearly north and south. When, however, they do make their appearance on the telegraphs in those parts, we are prepared to expect auroral manifestations when night arrives—and we are rarely disappointed. The deflections in their variations appear to coincide with the various phases of the aurora. On the branch line running from Ashford to Ramsgate these deflections have been a much more common occurrence, even when the other parts of the line were unaffected, and when no auroral phenomena were noticed.—*C. V. Walker, F.R.S.*

ON THE PATENT LAWS.

We have great pleasure in reproducing in our columns the following paper on the Patent Laws, by Thomas Webster, Esq., M.A., F.R.S., which appeared in the *Journal of the Society of Arts* on the 22nd instant, and we purpose laying before our readers the very interesting discussion which succeeded its reading at the Society of Arts :—

The Council of the Society having suggested that a discussion on the Patent Laws might be of service during the present session, I have much pleasure in preparing a communication for the purpose of facilitating the full consideration and discussion of the subject.

It is one of the peculiar characteristics of this ancient Society—the first and for a long time the only representation of practical science—that its comprehensive character permits it to take the lead in any movement relating to the Arts, Manufactures, or Commerce of the country. The committee to which "The Patent Law Amendment Act, 1852" is due met first in the house of this Society. Other committees of the Society have from time to time reported on this subject in the years 1850, 1851, and 1852, and the recent communication of the chairman of your Council to the Social Science Association, at its meeting last year, at Edinburgh, is a valuable contribution to the history of the progress of opinion on this subject.

It is not my intention on the present occasion to treat of the general jurisprudence of the subject, by entering on an elaborate discussion of the origin or grounds of the principles upon which property in the exhibition of mind, as embodied in material forms, may be considered to rest. The origin of such property, the grounds upon which it rests, whether on natural right, on policy, or expediency, the protection of such property by laws of the land, without which the name of property is but an empty sound, have been repeatedly treated of.

My object on the present occasion is to treat the subject practically in reference to the general policy of the patent laws, and with the view of ascertaining facts and eliciting opinions on certain questions which the consideration of the policy of those laws involves. That the subject has difficulties peculiarly its own is not to be denied; whether such difficulties may be greatly modified and lessened, if not altogether removed, is one of the questions at issue. Hitherto no attempt has been made to grapple with these difficulties, the provisions for this purpose contained in the Patent Law Amendment Act having remained in abeyance.

Considerable differences of opinion may be expected as to the most appropriate remedies for the admitted grievances, but I believe that should the discussion of the subject be fully exhausted, there will be a great preponderance of opinion in favour of the views with which the Patent Law Amendment Act of 1852 was proposed and supported.
